THIS (THE NINETIETH) VOLUME OF "THE GARDEN"

IS DEDICATED, BY PERMISSION, TO

MISS GERTRUDE JEKYLL, V.M.H.

MISS GERTRUDE JEKYLL is The Grand Old Lady of English Gardening. She is more than that, far more ; for her sympathetic understanding of plants, and of the men and women who cultivate them, gives her a unique position in horticulture to-day. She is the mother of the present day garden, and all gardeners are her children, who love her and pay her the homage that is her due.

On November 29th last Miss Jekyll was eighty-three. Throughout her long life she has been a keen gardener. As she herself says, she loves not only plants, but also their combination and selection in gardens, so that when planted they will make a place of peace and a garden of beauty. As a writer on gardens she wields an extraordinary influence, for she has raised the book on horticulture above a dry-as-dust tome, full of rules and lists of plants, to a volume that is so charming in its sympathy and deep understanding that it can be read with the greatest enjoyment by all who have the love of flowers at heart ; whether they are experts or beginners, specialists or amateurs.

It is owing to the enthusiasm of Miss Jekyll and Mr. William Robinson, another pioneer and the founder of this paper, that the evolution of the modern garden has taken shape. Previously gardening was done by rule of thumb and with a mathematical precision. They moved horticulture to a higher plane and, by using their imagination and with a sympathetic understanding of flowers, transformed stereotyped gardening into natural gardening.

Miss Jekyll's greatest work has probably been accomplished along the lines of the proper understanding and use of colour in the garden. Colour has always had a fascination for her, not the bizarre and magnificent use of broad splashes of crude tones that may be satisfactory in a sunnier climate than ours, but the careful blending and harmony of softer shades that make all the gardens in which she has wielded her influence a place of rest. As she herself has written : " Gardens may either be fashioned into a dream of beauty, a place of perfect rest and refreshment of mind and body—a series of soul-satisfying pictures—a treasure of well-set jewels ; or they may be so misused that everything is jarring and displeasing. To learn how to perceive the difference and how to do right is to apprehend gardening as a fine art."

We can only add our homage to that of all gardeners by dedicating to her this volume of THE GARDEN.

Lilacs in a front garden, 645
Lilies, Madonna 53; of the valley, 637
Lilium auratum platyphyllum, 58; candidum under pergola, 53; chalcedonicum, 473; Martagon album, 473; monadelphum szovitzianum, 472; philippinense, 53; Regale, 52, 438; szovitzianum, 392; testaceum, 53
Lily pool, 740
Lithospermum prostratum Heavenly Blue, 567
Lobelia Huntsman, 597
Loosestrife, 651
Lupin Downer's Delight, 598; polyphyllus hybrid, 382
Lupins in mixed border, 602
Lychnis viscaria splendens, 416
Lythrum roseum, 651

Magnolia macrophylla, 379; on wall, 217; stellata, 731
Maidenhair fern, 584
Marigold, fasciated stem of, 121
Marrows on hot-bed, 341
Marsh marigold, 253
Meconopsis aculeata, 250; Baileyi, 98, 436; hybrid, 474; integrifolia, 135; Prainiana, 115; pseudo-integrifolia, 96, 97; the ivory, 115; Wallichii, 474
Mesembryanthemum crassulinum, 461; tigrinum, 335
Mice, trapping, 720
Michaelmas daisies, 615; a border of, 655
Mimulus, 34, 743
Montbretias in a border, 143
Muscari under flowering cherry, 487
Mushrooms in frame on hot-bed, 225; on a hot-bed, 539

Narcissus angustifolius in Styria, 284; Cædmon, 483; Folly, 255; King Alfred, 430; Mrs. R. O. Backhouse, 349; Mulberry, 255; poeticus, 483; Quartz, 360; W. P. Milner, 496; White Sentinel, 255
Nasturtium, climbing, 353
Nepeta with antirrhinums, 345, 537
Nerines, hybrid, 11
New York Botanic Gardens, 178
Nigella, 22; Miss Jekyll, 568
Nymphæa stellata, 252
Nymphæas, flowering, 203; replanting in pond, 203, 204

Œnothera, 511; cæspitosa, 446; missouriensis, 417
Olearia semi-dentata, 127
Omphalodes linifolia, 265
Onion Ailsa Craig, 25
Onions, gathering and storing, 544
Onosma tauricum, 339
Orchis foliosa, 85
Oxalis adenophylla, 714; enneaphylla, 63

Pæonia officinalis lobata, 360
Pæonies at Kelway's nursery, 576
Palms, repotting, 243
Pampas grass, clump of, 685, 717
Paths, cinder, edged with santolina, 695; edged with mossy saxifrages, 175; grass and cement, 695; laying crazy paving, 29; woodland, 482
Pear Doyenné du Comice, 648; pyramid tree in flower, 660
Pears, cordon, 666
Peas, Sutton's Early Giant, 24
Pelargonium Mme. Crousse, 315; Paul Crampel, 231
Pelargoniums in baskets, 573
Pentstemons in a border, 494
Perennials, division of, 560
Pernettya ciliaris, 257; mucronata, 623

Pilot Border Gem, 553; herbaceous, 603; La Neige, 681; perennial, 237; subulata Nelsoni, 647
Phloxes, herbaceous in a town garden, 628
Phyllocactus blandum, 404
Physalis Franchetii, 628
Phytocma comosum, 497
Picea excelsa globosa nana, 234
Pink, Cheddar, 62
Pinks as an edging, 459; on a dry wall, 631
Pleiaanthus Lyallii, 78
Plan, annual border, 18; of fruit garden, 621; of garden, 535, 551, 569, 581, 599, 605, 622, 630, 661, 662; herbaceous border, 564, 676; of rose bed, 653
Plants repotting, 260
Platycerium alcicorne, 179
Polyanthus Greenway's Glory, 572; in woodland, 715
Polygonum affine, 669; campanulatum, 179; vaccinifolium, 696
Pond, water lilies flowering in, 253, 740
Poppies, annual, 22; Shirley, 17
Potato, clamp of, 606; Dargill Early, 57; freak, 701
Potentilla fruticosa, 467
Potting plants, 260
Primula chionantha, 135; conica, 133; denticulata, 20; fasciculata, 163; Florindæ, 313; Forrestii, 510; hirsuta, 347; involucrata, 145; malacoides Dwarf Eclipse, 209; marginata, 347; Mooreana, 133; obconica, 502; pubescens alba, 211; Reidii, 132; rosea, 709; Smithiana, 145; spectabilis, 104; stellata, 177; sulfureiscens, 132; Veitchii, 133; Winteri, 144
Primulas in the rock garden, 617
Propagation by cuttings, 453
Prunus laulia, 68; laurocerasus, 471; Pissardii, 623; rosea perodula, 294; serrulata, 730; triloba fl. pl., 267
Pterocarya rhoifolia, 431; stenoptera, 431
Pulmonaria azurea, 715
Pumpkin, 622
Pyracantha Gibbsii, 287
Pyrethrum Victoria, 367, 651
Pyrethrums at Kelway's nursery, 577; double, 22; single, 23
Pyrola rotundifolia, 239
Pyrus aria majestica, 554; Eleyi, 571; malus floribunda, 293; Vilmorini, 465

Ramondia, in a rock garden with ferns, 694; Nathaliæ, 69; pyrenaica, 372
Ranunculus, camellia - flowered, 83
Raspberries, pruning and planting, 640
Rev. Joseph Jacob, M.A., The late, 109
Rhododendron campylocarpum, 184; Duchess of Portland, 186; Edgeworthii, 184, 365; exhibition, 288; Forsterianum, 247; George Hardy, 698; ledifolium, 192; Loder's White, 699; moorland in China, 187; Nobleanum album Gills' var., 152; Pink Pearl, 699; præcox, 116; Wightii, 184, 185
Rhododendrons at Wallace's nursery, 437; bank of hybrid, 608, 747; exhibit of, 287; under trees, 110
Rhubarb, forcing in open, 684; planting, 59
Robber fly, 223
Rock bank, 282
Rock garden, design of, 508; exhibits of, at Chelsea, 299; on a bank, 520; path, 725; a town, 548
Rodgersia pinnata, 662
Root pruning, 601, 700; fruit trees, 636
Rosa bracteata, 421; Helenæ, 420; Hugonis, 421; Moyesii, blooms of, 549; Moyesii, fruit of, 549; setigera, 509
Rose garden, 506, 618; plan of, bed, 653; rambler, on arch, 632; rust, 504; weeping standard, 683
Rose, Varieties of: Albéric Barbier, 499; American Pillar, 749; Angele Pernet, 160; Austrian Copper, 421; Bedford Crimson, 624; Betty Uprichard, 337; Billy Boy, 384; Charles E. Shea, 619; Christine, 469; Coral Cluster, 613; Dame Edith Helen, 529; Everest, 397; Florence M. Izzard, 169; Independence Day, 619; La Tosca in beds, 533; Lady Helen Maglona, 397; Maréchal Niel, 336; Margaret Dickson Hamill, 469; Mme. Butterfly, 396; Mrs. Beatty, 614; Mrs. Henry Morse, 532; Orleans Rose, 613; Patience, 529; Sovereign, 168; Thelma, 274; William Allen Richardson, 337; Zéphirine Drouhin, 443
Roses, budding, 369; cuttings of, 410; exhibit of, 303; exhibit of at Holland Park, 555; green fly on, 309; hedge of, 498; in beds with delphiniums, 172, 602; on an apple tree, 682; on brick pillar, 683; on chains, 683; on pergolas, 507, 682; on pillars, 583; on wall, 402; ramblers covering a tree stump, 646
Rubbish destructor, 492
Rubus australis, 375; biflorus, 148; deliciosus, 85; quinqueflorus, 665

Salads, protecting early, 74
Salix magnifica, 79
Salvia dichroa, 67; nemorosa, 741; Sclarea, 84
Sanguinaria canadensis, 67
Santolina, edging a path, 695
Saxifraga Ada, 117; Boydii, 157; Burseriana, 6; bursiculata, 7; cochlearis, 568; Cotyledon, 158; decipiens grandiflora, 226; Faldonside, 157; Irvingii, 7; oppositifolia, 157; paradoxa, 285; Stracheyi, 21
Saxifrage, an encrusted, 7
Saxifrages, edging a path, 175
Scabiosa caucasica, 433
Schizanthus, 16; dark strain of, 499
Schizophragma hydrangeoides, 281
Scilla peruviana, 416
Seakale, forcing, 719
Sedum spathulifolium, 663; spectabile, 616
Seed saving, 466
Senecio laxifolius, 376
Show, Chelsea, exhibits at, 290, 317; Holland Park, exhibits at, 555
Shrubs, exhibit of, at Chelsea, 301; under trees, 111
Sidalcea Sussex Beauty, 687
Sink garden, 64
Smilax, training, 75
Snowdrops, 49
Soil, digging of, 608
Sorbaria arborea glabrata, 219
Spiræa Aruncus, 192; Henryi, 374; Lindleyana, 660; Veitchii, 103
Sprayer, Carter's Ideal, 394
Stachyurus præcox, 37
Stranvæsia salicifolia, 571
Strawberries, exhibit of, 321; exhibit of Laxton's, 625; planting of, 556
Streptocarpus Wendlandii, 117
Suckers, removing, 516
Sunflower, annual, 200
Sweet Pea Goldcrest, 26; Jean Ireland, 129; Royal Purple, 129
Sweet Peas, autumn sown, 575; exhibit of, 319; planting in trench, 107
Sweet Rocket, 403, 708
Sweet William Invincible, 83
Syncpsis sinensis, 37

Tamarix gallica, 350
Thalictrum dipterocarpum, 292
Thlaspi rotundifolium, 9
Thuya orientalis, 249
Thymus Serphyllum, 331
Town garden, 558, 629
Tomatoes, top-dressing, 355
Trellis, how to make, 655
Tricuspidaria lanceolata, 127
Trollius europæus, 279; Golden Queen, 651; Orange Globe, 644
Tropæolum speciosum, 206
Tulip, fasciated, 121; Golden Crown in border, 214; Kauffmanniana, 403; leaves attacked by scale, 413; Pride of Haarlem in beds, 214
Tulips, Darwin, in beds with forget-me-nots, 495, 649; diseased bulbs, 233, 234; exhibit of, 318; exhibited by Carters, 118; in beds, 486; in formal beds, 480; in a mixed border, 566; May-flowering in border, 481
Turnip, gall-weevil, 289
Turnips, storing of, 652

Venidium calendulaceum, 47
Verbascum phœnicum, 374
Verbena chamædrifolia, 417
Veronica Andersonii variegata, 580; spicata alba, 663
Viburnum dilatatum xanthocarpum, 8; macrocephalum, 79; 281; Opulus fructu - luteo, 570; rhytidophyllum, 521; Tinus, 3
Vinca difformis, 352
Virginian Stock, 407
Viola calcarata, 36; cenisia, 36; cornuta, 403; gracilis, 585; gracilis alba, 709; Mrs. Marrison, 171
Violas, cuttings of, 490; in beds with gladioli, 231; in border, 171

Wall, low retaining, 265; plants growing on, 113; pinks on a dry, 631; stone, Virginian stock growing in, 407
Wallflowers, 23
Water lily pool, 253, 740
Weevil, alpine plant, 283
Woodland path in spring, 482
Wulfenia carinthiaca, 285

Zenobia pulverulenta, 711
Zinnias, Sutton's exhibit of, 552

INDEX TO LETTERPRESS

Abelia Grebneriana, 219; Schumannii, 425
Abies grandis, 406
"Abol" Challenge Trophy, 250, 305
Acacia Riceana, 210; verticillata, 241
Acanthoimons, 207
Acers, 164; Japanese, 724; selection of, 436
Achillea tomentosa, 251
Achilleas, 461; for border and rockery, 741
Aethionema Dwarf Pink, 476
Aconitum variegatum, 680; Wilsoni, 21; Aotea rubra, 316
Adiantum emarginatum, 323
Æsculus Pavia, 418
Ailanthus, 316
Ampelopsis, 543; umbellatus, 266
Anthura coelestis, 9
Allium descendens, 451; Schubertii, 387
Aquilegia, from seed, 134; propagation by cuttings, 448
Arabis spinosum, 364
Amaryllis Belladonna, 604
Amateur Show, 379
Amazon Lily, 178
Anarrhinum bellidifolium, 503
Anchusa Rollea Dropmore var., 550, 712; Italica Opal, 712; myosotidiflora, 264, 305, 339; propagation of, 748
Anemone apennina, 485; Creagh Castle strain, 210; nemorosa Robinsoniana, 132; Seemannii, 266
Anemones, Japanese, 525; poppy, 296
Annuals, border of, 18; for cutting, 99; for hanging baskets, 34; for rock gardens, 114, 136; for the greenhouse, 508; hardy, 65; growing period of, 396; novelties in half-hardy, 81; preparing for, 728; transplanting half-hardy, 197; uncommon, 46; useful, 27
Anogramma glandulosum, 272, 409
Antheriums, 388; value as foliage plants, 452
Antirrhinums, autumn sowing of, 536; pricking out, 92; pricking out seedling, 212
Apple Rev. W. Wilks, 670
Apples, arsenic in, 219; dual-purpose, 632; picking and storing, 514; self-fertility and self-sterility of, 719; summer pruning of, 398; thinning, 341; unfruitful trees, 606; varieties of, 593; winter pruning of, 684
Aquatics, 252; for a small tank, 721
Arabis, 364; albida, 673; albida fl. pl., 633
Auraucaria imbricata, 366, 378
Arbor-vitæ, 249
Arbutus, 70
Arches, how to make, 671
Artemisia camphorata, 389
Arctostaphylos californica, 632; Manzanita, 238; Uva-ursi, 460
Arctotis breviscapa, 393
Arisarum proboscideum, 406
Artichokes, Chinese, 719; propagation of globe, 652
Arum lilies, 410; culture, 592; in the open, 335, 366, 422
Arum orientalis, 597
Asparagus, cleaning beds of, 572; how to make beds for, 556; sowing, 289
Aster Amellus Ultramarine, 597; elegans, 686; Farreri, 460, 639; grandiflorus, 728; King George, 644; Nancy Ballard, 622; Tradescantii, 628
Asters, collar rot in, 324
Auriculas, 4
Autumn colour in the garden, 582
Azalea indica, 193; indica Albert-Elizabeth, 181; Knaphill Pink, 323; Knaphill White, 322; rosæflora, 418; Valencia, 323
Azaleas, forcing of, 678; non-flowering a cause of, 193

Babianas at home, 457
Balsam, 316
Baneberries, 316
Banks, alpines for, 282; plants for dry, 381; shrubs for dry, 678; sunny, treatment of, 278
Basket plants in greenhouse, 205
Beans, 24; early crops, 745; late crop of dwarf, 398; runner, 566
Bearberry, 460
Bedding, propagation of plants for, 452; spring, 522, 633, 649; storing summer plants, 637; suggestions for spring, 566; suggestions for summer, 231; summer, 296
Beech, fern-leaved, 450
Beetroot, storing, 504
Begonia Ideala, 290; Rex, 612
Begonias, for baskets, 8; tuberous, starting, 60, 123; winter-flowering, 35, 735
Berberis brevipaniculata, 51; chitria, 409; flowering, 263; kansuensis, 272; Neubertii, 335; seedlings, 51; stenophyla autumnalis, 549; Vernæ C. Schneider, 206
Bignonia capreolata, 283
Birches, seedling, 89
Blackberries, cultivated, 116
Black currants, big-bud in, 685; reversion or nettle-head in, 328; varieties of, 665
Blue in the garden, 38
Bomarea acutifolia var. punctata, 323; Banksii, 272
Book Reviews—"Carnations for Every Garden and Greenhouse," 440; "Flower Scent," 36; Gladiolus Guide Book, 675; "Hand List of Conifers Grown in the Royal Botanic Gardens, Kew," 76; "Herbaceous Borders for Amateurs;" "Herbaceous and Other Ornamental Trees for Amateurs," 60; "Ornamental Trees for Planting," 76; "The Families of Flowering Plants," 76; "The Pruning of Trees and Shrubs," 228
Borders, advantages of mixed, 604; annuals for, 18; dry, by a hedge, 538; edging for herbaceous, 230; feeding, 658; flowers for, 22; north, in summer, 418; stone and rock edging for, 205; herbaceous, arranging a, 564; herbaceous combinations in, 324; herbaceous in spring, 172; herbaceous, perennials for, 602; herbaceous, plan of, 676; herbaceous renovating, 561; herbaceous, spring treatment of, 29
Bougainvillea, pruning of, 228
Bouvardias, 308
Bowling greens, from seed, 211
Brachyscma latifolia, 272
Brassicas for spring sowing, 212
Broad beans, 638; early, 588
Broccoli, 307; sprouting, 356
Brompton stocks, 350, 476
Brussels sprouts, early, 244; planting, 341
Bryanthus erectus, 711
Bryophyllum calycinum, 746
Buddleia Colvilei, 471; Forrestii, 543 globosa, 471
Bulbinella Hookerii, 685
Bulbs, after flowering, 107, 743; Cape, in the open, 353; Cape, treatment of, 288; early, 464; for the cold greenhouse, 557; for the rock garden, 538; forced, treatment of, 60; growing in pots, 100, 716; growing in pots and boxes 649; in pots and bowls, 515; lifting and storing, 395; planting, 586; planting in grass, 490; plants to grow with, 495; potting, 534; potting early-flowering, 438; what to plant, 486

Cabbages, 589; club-root in, 13, 289 pests of, 162, 560
Cacti, for amateurs, 5; interesting, 375
Cactus, flowers of, 404
Calluinthas, 84
Calceolaria John Coutts, 367
Calceolarias, 515
Callicoma serratifolia, 323
Callistemon citrinus var. splendens, 210
Caltha polypetala, 665
Camellia Sasanqua, 131
Camellias, growing in the open, 192
Campanula crenulata, 322; Donald Thurston, 425; persicifolia, 419; pyramidalis, 607; pyramidalis alba, 259
Campanulas, border, 499; for the rock garden, 41, 727; the taller-growing, 26, 73, 727
Cannas, 197
Carbolineum washes, 357
Cardamine pratensis, 103
Cardoon, 108, 398
Carnations, Border, 170; layering, 354
Carnations, Malmaisons, 122
Carnations, Perpetual, Dorcas, 322; Earl Beatty, 424; Hebe, 322; Laddie, 330; Beatty, 424; Hebe, 322; Laddie, 330; of the florist's shop, 190; repotting and stopping, 290; Rouge, 181; winter treatment of, 678
Carrot fly, 307

Digitized by Google

Carrots, late crops of, 572; ridding them of fly, 574
Cassiope selaginoides, 251; tetragona, 498
Cauliflower, White Queen, 59
Cauliflowers, 24; autumn treatment, 544; early, 92; planting, 588; protecting late, 684; summer, 123
Ceanothus Gloire de Versailles, 711; Henri Defosse, 451
Cedar, forms of the red, 524
Celeriac, 74, 108, 398
Celery blanching, 439, 544; final earthing up, 588; pricking off, 289; self-blanching, 92; summer treatment of, 307; trenches, making, 227

Post free on application.

Our Seeds have for the second year in succession gained a Record Number of Premier Awards.

During the past season, no fewer than **30 Gold Medals** were won at the leading Exhibitions in the kingdom.

SUTTON & SONS *THE KING'S SEEDSMEN* **READING**

Notes from Maidstone.

A NEW CHERRY.

AFTER having tested the new cherry, Triaux, for twelve years, we now introduce it with the certainty that it is a valuable addition to its class, as it ripens at the same time as the Flemish, but is very much larger and excellent for jam and bottling. Six feet Standards are 15/- each, and we also have two year Bushes at 10/6 each, and Maidens 7/6 each.

PLANTING IN SPRING

ALTHOUGH the seed list is the most important factor in horticulture during January and February, spring planting should not be forgotten. There seems to be a fetish among gardeners that all planting should be done in the autumn and that once Christmas is past planting is finished with for the season. This very prevalent idea is false, although it is difficult to find out how it has arisen, for most books on horticulture qualify such statements that planting is best done in the autumn by saying that it can also be carried out in the spring; and yet, however much may be said, many gardeners firmly believe that autumn is the only planting-time. It is only fair to state that there are certain plants, such as strawberries, irises, lilies and other bulbs, that should never be planted in spring, but their list is short. Some experienced gardeners, indeed, think it immaterial whether planting is done in autumn or spring.

The one argument for autumn planting is that there is usually so much work to be done in the garden during spring that many are thankful to find something to keep them employed during what would otherwise be a slack time of the year. This note is written owing to the fact that a number of letters have been received from readers to say that the hard weather has kept the ground too hard for planting and asking if the early spring is too late to refill a herbaceous border or plant shrubs. The answer is always No. Those who are lucky had time to dig up their borders before the ground became stone hard, and will reap the benefit, for frost is a great sweetener of old sour soil and this period of rest while lying fallow will do a great deal of good. Personally, I do all my shrub planting in the spring; if plants arrive during the winter months they are shoved into any odd corner of the garden to wait until I am ready for them, and I have never found that they come to any harm from their long wait, provided that they do not break into extravagantly early growth. The same thing applies to herbaceous plants.

Some people say that plants settle into their places during the winter and are ready to break into freer growth in the spring. There is not so much in that argument as many imagine. After all, the spring is considered the ideal time for furnishing a rock garden, and what does a rock garden contain but miniature replicas of what is found in other parts of the garden—shrubs, herbaceous plants, annuals, dwarf climbers and so on? If planting is well and thoroughly done, the actual time, whether autumn or spring, does not matter much. Much of the blame that is laid at the door of a wrong season, bad weather and so on is really due to hasty and careless planting; of this I am certain. In their haste to get the work done many people snatch on the first opportunity without looking at the weather forecast—whatever that may be worth—or considering whether the ground is too sodden or too cold, or if the plants came from a more congenial neighbourhood in Britain, or whether the ground has been properly prepared. Common sense has as much to do with planting as with anything else, and some people are afraid to let their common sense help their judgment and their judgment help their gardening technique.

Another point that influences spring planting is that many nurserymen grow at least a portion of their stock in pots and, of course, in this case planting should always be left to the spring, for it is distinctly dangerous to plant in autumn straight from a pot to the ground, particularly in such a climate as ours when we have little or no idea of how the winter is going to turn out.

This is a severe lecture with which to begin the New Year, but, as I say, it has come to our notice that some amateurs intended leaving their borders and shrub ground unfilled because the hard weather had made them miss what they considered was the only planting season. I hope that I have said enough to shatter this delusion. Most plants are much more elastic than one would imagine and, provided they are properly handled and treated, it matters little to them if they are planted in autumn or if they do not reach their final resting place until the New Year.

EARLY-FLOWERING SHRUBS

YEAR BY YEAR THE VALUE OF SHRUBS THAT BLOOM DURING JANUARY AND FEBRUARY IS BECOMING MORE APPARENT, WITH THE EXCEPTION OF THE FRAGANT WINTER JASMINE THESE ARE ALL LARGELY NEW-COMERS TO OUR GARDENS.

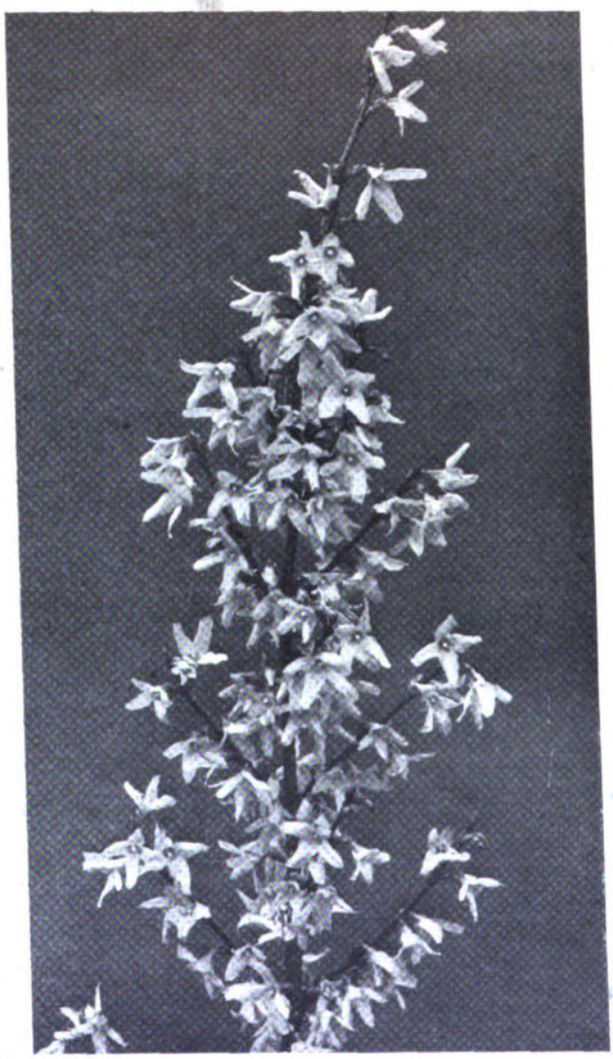
AT this time of year, when winter flowers are at a premium, the modern gardener looks more and more to winter-flowering shrubs, for in all normal seasons they add much needed splashes of colour. Although the numbers at the present moment are by no means large, they will doubtless increase as time goes on, for here is surely a good field for the hybridist. It is a curious fact how yellow is the commonest colour in the first flowers of the year, and blue the most predominant in late summer and autumn.

There are no rules about the grouping of winter-flowering shrubs, but there is one suggestion that can be made, namely, that they should not be scattered throughout the garden as single specimens. It is surely better to grow several plants together that flower at the same time, for, at any rate, a part of the garden is semi-clothed; whereas individual plants in full bloom are inclined to show up in high relief the nakedness of their surroundings.

Probably the two shrubs which are least bothered by frosty conditions are two viburnums—V. fragrans and V. Tinus, the common laurustinus. The former, although deciduous, makes a brave show from November to February and its flowers can stand twelve or so degrees of frost without having a pip frosted. Any deep loam suits it, provided that the soil never becomes too dry. V. Tinus is one of the most indispensable evergreens that we possess. Mr. Bean very wisely suggests that it might well replace many of the laurels, bays and privets that are so commonly used for screening and shelter hedges. It is certainly the brightest looking shrub during the winter months, with its close habit and shiny leaves. It is speckled with its white stars carried in loose cymes throughout the winter. The only warning that should be given is that in rich soil it will grow to a large bush and will crowd out its neighbours unless given plenty of room.

The old favourite, Daphne Mezereum, must not be forgotten for its branches laden with purple-red or creamy white sweetly scented flowers—there are two forms—are most attractive. For some reason or other, this daphne is more of a favourite in the cottage than in the large garden, perhaps because it is a slow grower and takes a long time to come to maturity; yet, withal, it is worthy of a wider distribution in larger gardens, if only for its fragrance.

The two witch hazels, Hamamelis mollis and H. japonica, are rapidly becoming favourites, and rightly, for they are eminently satisfactory shrubs. H. mollis, with rich yellow flowers, is the earlier to flower, and frequently opens about New Year's Day. H. japonica and its variety arborea are slightly later, but in February their curiously crumpled, sweet-scented petals set close on the wood are always an attractive feature. These two Asiatic species are really valuable in the garden, for their habit is good and their hazel-like leaves are neat and becoming when the flowering season is past.



A BEAUTIFUL SPRAY OF FORSYTHIA INTERMEDIA.

For lime-free gardens there are two ericaceous genera that have some members which are among the earliest flowering of all shrubs, the rhododendron and the heath. One deciduous species, R. mucronulatum, with reddish purple platter-shaped flowers, is very useful, as the flowers will survive several degrees of frost. It is a graceful shrub of about six feet, and as it flowers in January or February, according to the season, its utility in the garden is obvious. Rhododendrons, however, depend more on the season, and many hybrids and species, such as RR. moupinense, Nobleanum, Christmas Cheer and so on, which will flower early in an open season, are liable to be badly cut by frost. They, therefore, hardly come into the category of hardy winter-flowering shrubs.

Scarcely shrubs in the ordinary sense of the term, yet properly known as shrubby subjects, come two representatives of the heath family, Erica carnea and E. darleyensis. They are the earliest to bloom of all our winter flowerers, and continue to throw up their rich, rosy crimson to scarlet bells from December, through January, even until February if the weather conditions prove at all suitable. Planted either in beds situated on a slope and under trees, or in association with taller-growing shrubby subjects they look exceedingly well. The former provides dense, neat and compact mats of rich colour, which are a never failing source of attraction during winter. E. darleyensis is of a taller-growing habit, reaching about 2–2½ft. in height and, in addition to its sparkling blossoms, it is well furnished with attractive foliage, which will in itself be found admirable in relieving many a bare corner in the garden. Unlike their near relatives, the early-flowering rhododendrons and other heaths, both species grow readily in limy soils. In fact, they wax and grow fat and are of vigorous constitution when growing in lime. They are both of easy culture and need little attention after planting.

The winter jasmine probably ranks as the most popular of our fragrant winter-flowering shrubs. It is to be found in all gardens from north to south. It will be found occupying many positions—on walls, out in the open, or in association with other subjects—and it appears to accommodate itself readily to its ever changing environment, even to soil. To see it at its best is to grow it against a wall or a trellis, where its large and graceful, bright yellow, fragrant flowers provide a rich mantle of colour which will be found to tone well with the background. A few weeks later come the forsythias, another bright yellow-flowered tribe. The two species which deserve every consideration from those who intend planting early-flowering subjects are F. intermedia spectabilis and F. suspensa. Both are excellent shrubs, the former especially carrying abundant yellow blossoms on the naked stems, spelling the arrival of the spring. Both are admirable for wall decoration, and F. suspensa is eminently suited for draping trellis-work.

AN OLD SPECIMEN OF GARRYA ELLIPTICA IN THE CAMBRIDGE BOTANIC GARDENS. THE BEAUTY OF ITS GOLDEN PENDULOUS MALE CATKINS ARE REMARKABLE IN WINTER.

Speaking of shrubs for wall decoration recalls one which is all too rarely seen, namely, Garrya elliptica. One must be careful, however, in obtaining the male form, as then, in addition to the handsome foliage, one has the advantage of a fine show of the long dangling catkins of yellowish green flowers which clothe the bush from top to bottom. These appear in December generally and grace the shrubbery during the next few weeks. It is, perhaps, not so easy of cultivation as some of the others, and requires to have its little peculiarities attended to in the shape of a sheltered position and soil; but after that it grows happily from year to year.

Among our early shrubs is one—Magnolia stellata—which deserves all the good things said about it. Its pure white starry blossoms appear towards the end of March, and, although they show up in all their purity for two or three weeks if the weather is kind, they suffer readily from late frosts, which causes considerable disfigurement. A sheltered position is, therefore, called for, so that it may unfold its blossoms unharmed from the vagaries of our climate. It is, indeed, a handsome bush of neat habit and is full of charm when seen with its dark branches studded with the pure white stars.

THE SHADY BACK GARDEN

NO type of town garden is more difficult to deal with than the long and narrow one to be found at the back of a many-storeyed house in a row which shuts out all, or nearly all, the sunshine. Such a garden is generally bounded by walls which, oddly enough, instead of affording shelter, in nine cases out of ten make the wretched little plot into a sort of tank round which all the winds of heaven swirl. It is quite possible—I know it from experience—to walk from the end of such a garden towards the house with a gentle zephyr breathing on the back of one's neck and to be met at the half-way point by an icy and vicious gale blowing in one's face. Between the draughts and the lack of sunshine it is no wonder that many plants droop and die, or that the disheartened owner should finally abandon the place to weeds and cats.

It is, however, possible with patience and perseverance—plenty of them are wanted—to make something of a shady back garden. To begin, the customary "lawn" should be eschewed, for no matter how carefully laid and tended, it will become, sooner or later, a moss-grown and grassless eyesore. Far wiser is it to be content with borders and beds divided by paved, bricked or gravelled walks, but it is not proposed to deal here with the planning of the garden but rather with what may be grown in it.

Ferns and nothing but ferns are what one usually finds in the shadiest part of the shady garden, which is invariably that next the house. These are all very well provided it is remembered that there are other hardy ferns besides Lastræa Filix-mas. The addition of even the lady fern and hart's-tongue in two or three of its varieties to the male fern will be a considerable improvement. Combined with the ferns may be Ruscus aculeatus (butcher's broom), Hypericum calycinum and the vincas, large and small, blue and white. There are a couple of spurges, too, which will do well in such a position. One is the native Euphorbia pilosa and the other is believed to be E. daphnoides. It has tassels of yellowish green bracts and increases rapidly.

At the back of the borders a few climbing roses may be tried, but they must be trained on poles tall enough to allow them to get well above the wall, when they will bloom tolerably well. It is useless to attempt to grow either bush or standard roses under such conditions. On the wall itself Cratægus Pyracantha will produce its scarlet berries abundantly, and there are three jasmines that tolerate shade, to wit, J. officinale, J. nudiflorum and J. revolutum, although the last named will not flower as freely as in a sunnier spot. Ivy is often seen covering the walls of shady gardens. It is not desirable, however, for not only does it lack cheerfulness, but it is a harbour for snails and other pests.

There are many good plants that will thrive in a sunless, or almost sunless, border, provided that the soil is thoroughly well dug and prepared and does not consist mainly of builders' rubbish after the manner of too many town gardens. Foxgloves, the taller variety of Solomon's seal, Thalictrum aquilegifolium and Senecio tanguticus will be suitable for the back row, where also the cimicifugas, C. racemosus and C. cordifolia, may find a place if the soil be not too dry for them. Then, for the main part of the border we can have Japanese anemones, pink and white; Spiræa palmata and S. filipendula; Trollius europæus and T. asiaticus; Symphytum caucasicum and the native S. officinale; Astrantia major; Tradescantia virginianum, purple, rose and white; Funkia Sieboldii (beloved of slugs, alas!); Epimedium pinnatum and Cardamine pratensis fl. pl., the double lady's smock. The two last-named, however, require a deep moist and rather heavy soil, such as is rarely found in a town garden. Most campanulas dislike shade, but C. alliariæfolia thrives in it and C. latifolia does not object to it, although it does to lime in the soil. For the edging of a shady border there is nothing better than the ever-useful London pride, which will stand anything except a prolonged drought; but Asperula odorata, the common woodruff, is also suitable for the purpose, and its little white flowers are very pretty in a mass.

A rockery—an objectionable word, but one for which there is no synonym—can be managed even in a shady garden. Lysimachia Nummularia—the gay little creeping jenny—and Corydalis lutea will be quite happy without sun, or with only an occasional gleam. Corydalis bulbosa will also live and flower, but is less easy to establish than C. lutea. The common "mossy saxifrages" will increase abundantly, but will flower sparsely if at all, and without sun they seem to be more subject to the fungoid disease which disfigures them with black patches. Arenaria balearica, on the other hand, is only thoroughly contented in shade, and it makes the best carpeting plant under such conditions. A hardy little plant for either the rockery or the front of the border is Chrysogonum virginianum, which will go on producing its bright golden starry flowers all through the summer if it is well watered in dry weather. Ramondia pyrenaica, of course, blooms its best in shade if it is placed according to its liking, in a cranny between stones. Tiarella cordifolia may be tried with some prospect of success; and the Welsh poppy, Meconopsis cambrica, will flourish anywhere, although it may not seed itself quite so lavishly in shade as in sun. The orange form of this pretty and good-tempered little poppy is the best.

In nooks and corners of the rockery may be planted clumps of cyclamen, especially C. neapolitanum, Anemone hepatica and A. sylvestris, Leucojum vernum and L. æstivum. Some of the little daffodils, N. triandrus and its hybrids and N. cyclamineus may also be tried here, although the success of the latter is doubtful.

A shady back garden needs constant attention. Without the healthy influence of the sun the soil is apt to get sour and stagnant and, if damp, to develop liverwort and other unpleasantnesses, hence the necessity for frequently stirring the surface with a fork. An occasional dressing of lime should not be omitted if the soil is at all lacking in it.

R. E. HEAD.

AURICULAS AND THEIR USES

CERTAIN varieties of Primula Auricula have been christened by popular fancy "Dusty Miller," as they are powdered all over with a white powder, or farina, resembling flour. At one time this plant was very much more in evidence than is the case to-day. Not all members of this family, however, are covered with the farina which is characteristic of many varieties. Even among those closely resembling one another it is in evidence on some and absent from others. Those covered with farina are known as show auriculas, and those destitute of it are called alpine auriculas.

Some varieties are native to this country, or rather, to certain localised parts of it; while other varieties must be searched for in the wild state on the mountain ranges of Austria, Switzerland and France as well as in the Caucasus.

Primula Auricula will thrive in the smoke of the town, and though it prefers country air, it need not be left out of any town or city garden.

Alpine varieties offer a splendid selection of colours. There are varieties with beautiful golden centres, those with centres of white, others of cream and some of pale yellow. Then there is another group the flowers of which are attractively shaded, while self-coloured flowers are also in evidence. There are double-flowered varieties and there are laced varieties, all of which possess some distinct charm.

Among the show auriculas there are green-edged, grey-edged and white-edged varieties all bearing the flour-like substance.

Primula Auricula likes a well drained friable garden soil, with some leaf-mould and some old manure added. The soil should be on the heavy side, as these plants scarcely ever do well on light soils.

Auriculas are excellent for the rock garden, cool greenhouse or for beds. Show auriculas are more suitable for growing inside as the farina is liable to be damaged by rain when they are in beds outside.

Digitized by Google

ONE OF THE FINEST SHOW VARIETIES OF PRIMULA AURICULA.

Auriculas do not like much heat, and those varieties that do best grown in a greenhouse will thrive with very little additional warmth. To give too much is worse than giving none, as the natural home of this plant is on the cold higher lands.

Both the florists' type and the alpine auricula may, if desired, be grown as garden plants, but the latter is far more suitable as well as far more beautiful used in this way. The alpine auricula is of a free habit of growth. The flowers are of two colours, and the variety which may be obtained greatly adds to the value of this plant in the garden.

When growing auriculas from seed, it should be remembered that plants obtained from seeds which germinate quickly are often weaklings.

The seed should be sown during March in pans in a light sandy compost. Press the seeds into the soil and then lightly cover with sand. The pans should be placed in gentle heat, and when about four leaves have formed the seedlings should be pricked off into boxes. By June place the boxes in a well ventilated frame and shade from strong sun. In September or the beginning of October those required for flowering in a cool greenhouse should be potted and the remainder planted outside. Choice auriculas are propagated by division and not by seed. The old plants should be lifted at the end of June and the offsets potted. These pots should remain outside in a sheltered position until there is a danger of frost, when they should be removed to a cool house.

The auricula is a plant which will not do as well in bright sunlight as it will in a part of the garden where it is partially shaded. When the plants are ready for the final planting out this should be remembered.

The soil in which the plants are to find a home should be prepared by the addition of both leaf-mould and cow-manure. Strong plants will look well and do well as an edging to borders. The usual distance apart for these plants is about 6ins., and they also do well in the rockery.

It is not necessary to lift auriculas every year. They may be left untouched for three years, at the end of which time they should be carefully lifted, divided and planted out again. This work should be done after they have flowered.

Early in March the first of the blooms will be seen outside, but April is the month during which the flowers are at their best and they will continue to bloom during the whole of May. Sometimes they will bloom again during the autumn, but they can scarcely be said to make a show at this period.

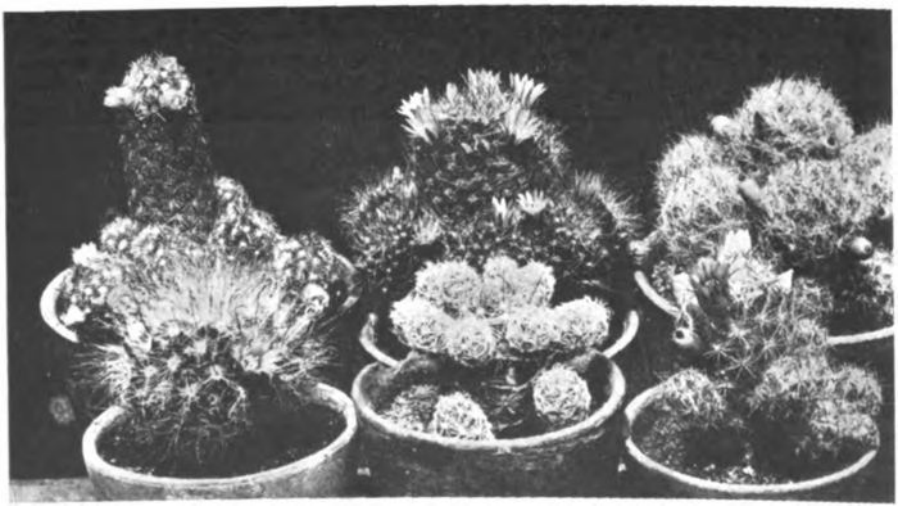
Although, as has been already stated, the alpine auriculas are generally accepted to be the best for garden purposes, other varieties may be so used if desired.

Among the white-edged varieties are Guy Cranfield and Acme, while the grey-edged include Richard Headley and Geo. Lightbody. Among the selfs may be mentioned Favourite, Harrison and Weir; while the green-edged include Prince Charming and William Smith.

There is a wide choice among the alpines, of which Firefly, Majestic, Phyllis Douglas, Prime Minister and St. Vincent are worthy of notice, as are also Silverwood, with its white-eyed flowers with their bright crimson edge; and Pilatus, with its yellow-eyed flowers. These two have a maroon body with a margin of purple, and are somewhat newer than hose mentioned earlier.

CACTI-GROWING FOR AMATEURS

CACTI-GROWING among amateur gardeners seems to be increasing in popularity, and these plants are certainly worth cultivating. The writer has successfully grown cacti for over ten years, and can assert that not only is the growing of these queer plants highly interesting, but also entertaining. There is always something fresh, something unexpected in growing cacti, and one has an almost limitless range of plants to choose from, some of which bear flowers that in beauty and magnificence are equal to any to be found in the whole realm of plants. Then, again, some of the most repugnant flowers, which smell horribly and have the appearance of putrid meat, are grown on cacti. Size is also in variety; for there are miniature cacti, no larger than a hazel nut, and the gigantic cacti as seen at Kew Gardens, 60ft. high. The writer has also seen on the south coast of Cornwall, in a garden, a gigantic specimen of an Agave cactus, growing out of doors, of course. It was about 20ft. in height with stems about 8ft. long and 2ft. in circumference. The plant was covered with gorgeous masses of small yellow blossoms, and the remarkable point about this kind of cactus is that after flowering the plant dies, yet these monsters do not flower until they are about 100 years old. So it can



THE BEAUTY OF TINY CACTI WHEN IN BLOOM.

Digitized by Google

be gathered this cactus was of a great age.

The cacti shown in the illustrations were grown by the writer in an ordinary English cool greenhouse.

The question of soil comes first. This should be made up of fibrous loam and coarse sand, and it is advised to mix the proportions exactly to ensure best results. Two parts of the loam to one of sand, and to this should be added a little leaf mould and crushed brick or lime rubbish. The idea, of course, is to copy the native soil of the cacti as nearly as possible, for by far the majority of cacti grow in the hot, arid and stony wastes of Mexico and central America.

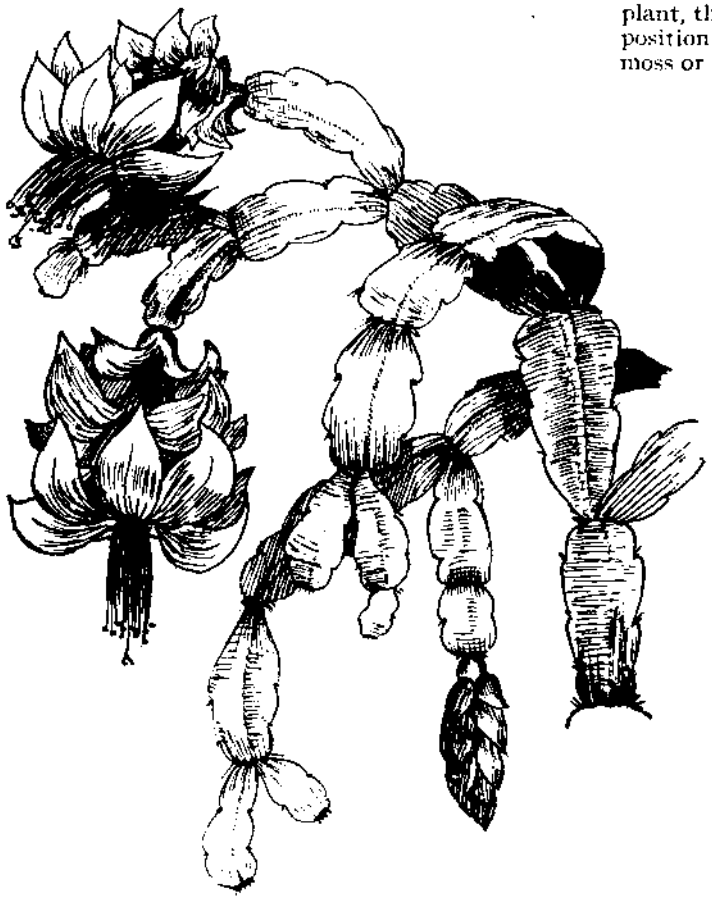
Having mixed your loam, make sure of ample drainage in your pots by first filling a third of the pot with broken up pot material and a few pieces of charcoal. This drainage is essential, as any stagnant moisture in a pot is most harmful, and no cactus will thrive under such conditions.

The various cuttings, seedlings or off-shoots can be purchased from any good horticulturist.

During winter most cactus plants require very little water, as this season is a period of rest and inactivity with the majority. But during the summer, plenty should be given. The best method being, either to shoot a syringeful over it so that the water falls like rain, or else to stand the pot in a pan of water, with the water below the top of the pot, and soak for several minutes, then remove.

Cacti, of course, require all the sunshine they can get, but at the same time, care should be taken in turning pots; this should be done gradually, or else a too sudden exposure of an "off" side may injure the soft tissue. In winter the plants will be safe in the unheated greenhouse provided actual frost is barred. Should the weather become very severe, paper placed loosely over the plants will protect them, and this should be done before retiring if there are prospects of a very cold night.

A point that might be mentioned is, never permit water to drip continually on your plants, especially the phyllocacti, as this will cause the stems to rot and patches here and there will turn brown in colour and become soft gradually withering away. Also this decomposition is liable to spread along the stem, and is difficult to check. One has to become a plant surgeon to stop the decay effectively, and with a sharp knife cut away all the brown on the plant, then replace on the shelf in a sunny position, and the cuts will heal. Should moss or green slime appear on the outside of the pot, this denotes defective drainage and should be seen to. The most effective cure, of course, is re-potting, using dry, fresh soil, and then place in a dry spot in the greenhouse.



THE GRACEFUL WINTER-FLOWERING EPIPHYLLUM TRUNCATUM.

The opuntias are the well-known pear-shaped cacti, and there are 150 species of this genus. Large areas of Texas are covered with these grotesque-looking plants.

One of the illustrations is of a group of mamillarias, and as can be seen, these are in flower.

I can also recommend the echinocereus cactus. Many of which bear large flowers of brilliant hues and many are also sweetly scented.

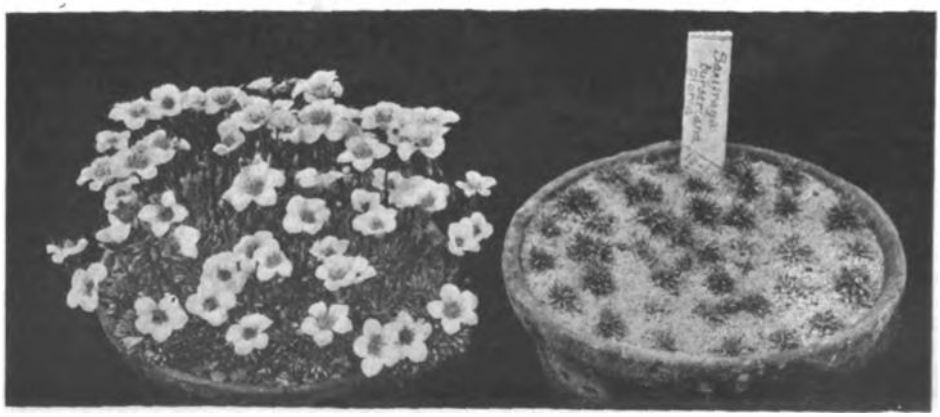
Phyllocactus are perhaps to be recommended more than any, as they are quite easy to cultivate and will grow in rooms (such as a dining-room) and will produce magnificent flowers regularly each year.

The epiphyllum is a beautiful and distinctive genus. As the plants are of a drooping nature, hanging baskets suit them best. Most of this genus flower in winter, and they require a moderate amount of moisture and a temperature of 50° to 55°.

The amateur will find his enthusiasm for cacti culture increase as the plants continue growing, and, as stated, there is practically an endless variety for him to choose from.

SAXIFRAGES IN THE ALPINE HOUSE

THE alpine house provides an unfailing source of interest during the early spring months. Many alpines succeed admirably under such conditions, and produce, from January onwards, countless flowers as spotless as they are beautiful. The main object of the alpine house is to provide protection against inclement weather conditions. Fog, snow, wind and rain damage considerably, and sometimes kill, certain of the alpines; but these, if grown under glass, for the greater part of the year give abundance of clean bloom. One of the cheapest and easiest of plant houses to run is the alpine house. It requires no heat, so that there is no stoking, and, as the pots can be plunged outside in ashes during the summer months, tomatoes or flowers can be grown in the houses during that period. The type of house which is most suitable is a low span-roofed house in an open position running north and south. Provision for ample ventilation is absolutely essential for successful culture of alpines inside, and a damp, stagnant atmosphere should be avoided at all times.



A CHOICE SUBJECT FOR THE ALPINE HOUSE, SAXAFRAGA BURSERIANA.

Digitized by Google

Saxifrages are particularly useful and amenable to alpine house treatment. Their diversity of form and colour make them particularly attractive.

The essential points in the culture of saxifrages under glass are airy conditions and a suitable compost. A damp, warm atmosphere is fatal to these plants. Most of the saxifrages succeed best in pans, either in seed pans of 6ins., 8ins. or 10ins. diameter, or in square propagating pans. A closed staging consisting of slate slabs is the best. This should be covered with a 2in. layer of fine coke breeze and the pots arranged in colonies thereon.

The compost should be gritty and well drained. Limestone should be supplied in the form of lime chips, old mortar rubble or broken oyster-shell. Firm potting is necessary. Watering needs special care, particularly during the winter months, when little will be required. From the end of May onwards saxifrages should be plunged up to the rims of their pots in an ash bed situated outside in a position exposed to full sun. Propagation is carried out by means of cuttings inserted in a very sandy compost in a frame. Saxifrages root most readily—in fact, small pieces pulled off the plants and put directly into the cutting frame root and grow rapidly. The accompanying illustration shows the size of a number of saxifrage cuttings at eight months old, and also the development of these into a well-flowered clump twenty months after propagation.

Although the autumn is the best time to begin a collection, there is no time, with the exception of the height of summer, when a start cannot be made.

Saxifraga Burseriana is one of the earliest and most beautiful of the kabschias. It forms mats of silvery leaves, and, on short stems of not more than an inch or so in height, countless large pure white flowers are formed. S. Grisebachii and S. Grisebachii Wisley var. are both excellent. These produce during February arched crimson flower spikes rising from small rosettes of silvery foliage. S. Myra is a beautiful hybrid of the kabschia habit, with short-stemmed cherry-coloured flowers. S. Boydii alba, S. bursiculata and S. Boryi are all handsome plants with white flowers. The round solid flowers of S. Faldonside are a most attractive clear yellow.

S. Irvingii is a delightful hybrid from S. Burseriana. It produces delicate pink flowers in great profusion during April. A most showy plant is S. apiculata with its primrose yellow flowers rising from green rosettes. S. lilacina is a Himalayan species, dwarf and compact in habit. The silvery grey mats of foliage are covered with clear lilac bloom.

The most outstanding of the encrusted section is S. longifolia, the queen of saxifrages, which, when in full flower, produces arching stems of 1½-2ft. long, covered with myriads of white blossom. S. Aizoon and its many forms are attractive and easy to manage. S. cochlearis minor produces hummocks of greyish rosettes and pure white flowers on reddish stems, and S. De Ramsey is a distinct and lovely hybrid with white flowers.

S. BURSICULATA, WITH HANDSOME WHITE BLOOMS.

NOTES OF THE WEEK

A NEW AND NOTEWORTHY VIBURNUM.

VIBURNUM DILITATUM XANTHOCARPUM is a yellow-fruited seedling sport which originated a few years ago in the nursery of J. H. Bowdistch at Pomfret, Connecticut. Like its parent it is a deciduous shrub of neat compact habit, growing from 3ft. to 5ft. high and more in diameter, with many thin but rigid ascending hairy stems and an abundance of dark green foliage. The leaves are obovate and abruptly pointed, about 3ins. long and 2½ins. broad, and in autumn are tinted vinous purple. The flowers are all perfect, creamy white, small and borne many together in flat 3in. to 4in. broad corymbs at the ends of the branches and branchlets. The fruits are lustrous, pale yellow, ovoid and very freely produced. As the leaves turn the fruits shine like old ivory beads. Less handsome in the autumn than its scarlet-fruited parent, this sport is a good garden plant, perfectly hardy and a useful addition to the limited list of yellow-fruited shrubs. It is a curious fact that outside the Opulus group this Asiatic V. dilitatum is the only species in which yellow fruits are known. —E. H. WILSON. *Arnold Arboretum, Harvard University.*

A NEW YELLOW-FRUITED VIBURNUM FROM AMERICA.

BEGONIAS FOR BASKETS.

BASKETS, filled with well grown and carefully selected flowers, are recognised by most gardeners as of great value for decorative purposes and extremely useful to lend increased charm to artistic design, but they are open to the criticism that they lack variety and have a sort of sameness which detracts from their beauty. I would, therefore, draw attention to the fact that there are special varieties of what I might call "pendulous begonias," which grow well in the ordinary basket, and flower profusely and are undoubtedly pretty. We have grown them for years, just a few, it must be admitted, and the old varieties are still favourites, improvement evidently being a slow process in these flowers.

Fleur de chrysantheme was one of the first we introduced, and it is still holding its place; the flowers are salmon pink and borne freely. Stella is another old kind, a delicate shade of scarlet, with long narrow petals of distinct form. Golden Shower, aptly described as similar in tint to the rose W. A. Richardson, is of great beauty. Alice Manning was the first yellow we had and it is still grown; Starfish and Gladys are equally old, but still good.

Of the newer sorts we fancy Cactus, a delicate pink; Corallina, a coral pink; and Lena, soft crimson. Rosina and Venus are, perhaps, not so satisfactory as we would like them to be; the former has ribbon-like petals of a new rosy shade and the latter is white, unfortunately with a greenish tinge.

The best way to grow these plants is to put three tubers in a medium-sized basket, and three of any one variety is probably enough. A rich, turfy loam is the base of the compost, and it must be made firm within the moss in the basket; the plants, too, must also be planted firmly, the tubers being just covered with soil.

Care in watering is very necessary, especially in the early part of the season, and the soil must never become sodden and sour. Syringing in moderation keeps the basket moist, and must not be omitted; this obviates watering in great measure, but loss is certain if the soil is allowed to become too dry.

Plants will be inclined to run to flower prematurely and, to prevent that, constant pinching should be resorted to. By doing this, growth is stimulated and the strong plants secured flower freely and well when allowed to do so.

Stems do not droop much until they become heavy with blossom. When the buds begin to show colour, feeding may be resorted to and undoubted benefits obtained; remove fading flowers.—CLYDESDALE.

PENTSTEMONS AND ALYSSUMS.

THE fashion, for quite a number of years, has been to plant largely one kind of plant in a bed or border, so that it occupies a considerable space of ground. The result is that we get very effective and impressive displays. Following on these lines, I would suggest, for an easily managed and comparatively inexpensive summer bed, to fill up the space with Pentstemon Newbury Gem in April, making a sowing of any dwarf-growing white alyssum at the same time for an edging.

Pentstemons are useful and easily managed plants, thriving in any fairly good soil with the minimum of attention. Their floriferousness, of course, is well known, and many are the varieties in cultivation, all more or less of great beauty. The usual mode of propagation is by cuttings, and these should be inserted in light sandy soil in a cold frame.—DAVID ARMSTRONG.

MONARDA DIDYMA COCCINEA (RED SAGE OR BERGAMOT).

BERGAMOT or red sage is a native of Pennsylvania. In olden days it was beloved by peasant women and ladies of high degree for its beauty, its healing properties and its power to keep away moths and other insects. Nowadays its virtues are so forgotten in England that it is difficult to solve its identity! *Sic transit gloria mundi!* Nevertheless, bergamot can still be found in some country gardens in Britain.

In France it is a common garden plant, and in Brittany (where it is found in almost every garden) it attains to the dimensions of a shrub. In that country its virtues are still widely known and appreciated.

Like most other garden shrubs, Monarda didyma coccinea has been improved upon, and two new varieties—Monarda Cambridge Scarlet and Monarda fistulosa (with rose, violet, purple or white blossoms)—have been produced.

The sprigs or leaves of the bergamot, and of all other aromatic members of the labiatæ order (such as the salvias, rosemary and lavender) are infused and made into poultices for the cure of all gouty and rheumatic diseases, and also to soothe and prevent coughing in cases of bronchitis, chronic coughs and whooping-cough. Sprigs of red sage or of any of the above-mentioned plants, if infused in hot water in the bath for a few minutes before the bulk of the water is turned on, will quickly relieve the bather who suffers from sciatica, lumbago, gout or rheumatism or is merely aching from over-tiredness.

If the leaves of bergamot are dried, rolled up in cigarette-paper and smoked, they will be found to give great relief to those who suffer from asthma.

It is the oil contained in the green parts of these labiates which endows them with their healing properties.

Mrs. Ewing (in "Daddy Darwin's Dovecot," I think) mentions that on Sundays the peasants wore sprigs of bergamot in their buttonholes. I have read elsewhere that in some English villages the men always wore bits of this plant at weddings which took place in the summer.

Red sage blooms from June to October, and, whether in its old form or in the new varieties, is a delightful addition to the herbaceous border. It is easily propagated by cuttings in the autumn or by division or from seeds in the spring. Bergamot has a habit of layering its lowest branches of its own accord as they grow just above the level of the soil.—VICTORIA SLADE.

IBERIS GARREXIANA.

THE "English Rock Garden" gives Iberis Garrexiana as a rare local form of Iberis sempervirens, blooming a little earlier and having a laxer habit. Distinctions so evanescent as these are not much wherewith to vouch for a separate species, knowing, as we all do,

Digitized by Google

how plants vary in different gardens and even in different sites in the same garden. A catalogue which I retain as a book of reference gives I. Garrexiana as forming a miniature evergreen bush—which is just what I. sempervirens does. Another work in six lusty volumes states that the variety Garrexiana is "preferred by many"—which seemed a reflection on my own acumen, as I could not discover how one species differed from the other. At last I fell in with Burnat, who had made a study of the matter, and who makes I. Garrexiana of Allioni equivalent in all respects to I. sempervirens of Linnæus. After examining specimens from the Pyrenees, the Maritime Alps, Italy and Greece, Burnat decided that he was unable to distinguish two varieties. That was in the 'nineties; and a decade later Halácsy simply gave I. Garrexiana of Allioni as a synonym of the better known name, without any argument about it. It must, therefore, nearly be time for the name Garrexiana to disappear from catalogues and gardens, even though the "many who prefer it" may be disappointed at ceasing to possess a rarity. Any visitor to the Riviera in April may collect the plant in the hills north and north-east of Bordighera. —E. E. T.

TWO MOUNTAIN CRUCIFERS.

CRUCIFERS are a prolific race and, with exceptions, rather dull. They give us cabbage and lettuce and a host of wandering weeds, but, somehow, one does not connect with them the idea of alpine treasures. It is true that among them we find beauty in the form of wallflowers, stocks and that stop-gap of the rock garden, aubrietia; but one does not expect to find such diminutive grace as Draba pyrenaica. He bears the stamp of mountain breeding, and a true mountaineer he is, for I have followed him to heights where all except Saxifraga oppositifolia, the androsace and Ranunculus glacialis have given up the struggle.

The plant forms a close mat of green rosettes about an inch high, which individually give one the idea of a tiny mossy saxifrage till it comes into flower, when it breaks out into a sheet of tender pale mauve. The picture here shows a mat I photographed at about 8,000ft., and the plant was 2ft. across, looking in the distance as if someone had dropped a mauve handkerchief on the ground. There was any quantity of it about, in patches large and small, and among them I found a rarity, a pure white form which seemed to be more compact in growth than its neighbours. In cultivation, draba is not a beginner's plant, as it is easily mishandled; but it is not in the category classed difficult. It wants sunshine and not too dry a position, light soil (preferably a semi-scree mixture) and good drainage: without this last, or in sticky soil, it will miff off. Given these requirements it will behave as a little gentleman should do and be a pleasure to those who behold it. Its demands, after all, are not very outrageous, and, given them, it will flower gaily every year, and each year will see its girth increase. There is one other command it gives us—that its roots shall not be disturbed during the growing season.

Another choice crucifer is Thlaspi rotundifolium — even Farrer, who would consign all crucifers to the rubbish heap, was warm in praise of this plant, and it certainly merits it. Out of flower one would pass it by as a dull weed, with, perhaps, a little surprise at the place it chooses to inhabit, for it lives in the high screes and seems to prefer the most arid, without a grain of soil between the stones—the sort of place Viola cenisia chooses: in fact, I have found them growing in quantity side by side. But when in flower it commands attention. Be one's goal never so far and the climb never so stiff, yet one must stop a while to look at Thlaspi rotundifolium. The flowers are lilac, neither mauve nor pink, but true lilac, and the scent is delicious. The prescription to keep it in health at home is a scree with drainage above suspicion, and never allow the plant to want moisture at the roots in summer.

The mention of the scent of Thlaspi rotundifolium brings me to a subject which should hardly come under the heading of this note—it is fragrance in the rock garden. I must admit that I often refer to scent in flowers, but I consider that for a rock garden plant to be usefully fragrant one should be aware of it in passing by, and not have to go on all fours and get one's nose down to it. Now, daphnes and some dianthus fulfil this requirement; in passing them one will turn round and wonder what is smelling so sweet—Trifolium alpinum, to take at random an otherwise valuable plant, does not do so, for in anything less than a 2yd. mat one would not be conscious of its fragrance. With border plants one demands a different standard, for one can get down to them without trouble. —A. GAVIN JONES.

THLASPI ROTUNDIFOLIUM IN SCREE AT 8,000 FEET.

DRABA PYRENAICA, ONE OF THE CHOICEST OF HIGH ALPINES.

A MARGUERITE YEAR.

THIS has been a glorious year for the plants known popularly as marguerites, and among them we include that one known as the Blue Marguerite, Agathæa cœlestis. As everyone knows, this plant is only half-hardy; indeed, many growers never try it in the open and are content with it in a cool greenhouse, where it flowers for a long time in glorious profusion.

To get plants for bedding next season, cuttings should now have been taken and rooted in pots of sandy compost. For a succession in the greenhouse, more may be taken in spring, or, indeed, as occasion calls; these, when rooted, are put into small pots and potted on until flowered in seven-inch size. The compost need only be a sandy loam and, when growing, the plants must have plenty of sun. Bushy sturdy specimens become an absolute delight when in flower.

When grown for open border work the blue marguerite may have treatment similar to that given the bedding geraniums. Not always are we quite satisfied with results in the north, but when we get a good year like this, there is no call for criticism.—H. H. A.

THE JAPANESE TOAD-FLOWER.

A PLANT seldom grown in the garden and one not likely to become a favourite, is the Japanese toad-flower, or Tricyrtis, yet it is one which flower lovers should know something about, if only for the sake of avoiding it. No doubt the toad-flowers would find a certain degree of favour if they flowered in good time, but unless given a warm place they will not flower before frost comes. They are curious looking plants withal: generally about a foot high, rather arching in habit, with pointed leaves and flowers from the axils of a curious form, rather after the fashion of the lilies, but infinitely less beautiful and of a curious livid hue, spotted all over—whence the name of toad-flower. There are several species, but the one said to be the finest is not in commerce. From one's experience of T. macropoda, T. hirta and T. pilosa, one has more than grave doubts as to the value of the unintroduced species. Those who may like to try the tricyrtis after this, may note that it likes a soil similar to that favoured by the trilliums, but that it must have a warm place, as previously suggested, although a woodland plant at home.—S. ARNOTT.

RHODODENDRON GRIEVEII.

ALTHOUGH the genus rhododendron has, during the last decade, given us many beautiful hybrids, few, especially of the dwarf kinds, are more lovely than the above-named hybrid, which was raised some years ago by the late James Grieve, a noted Scottish horticulturist. In stature it stands about midway between its parents, namely, R. ciliatum and R. glaucum, forming low, sprawly and somewhat twiggy bushes. The flowers, which are so freely produced in drooping clusters during late spring, are a little wavy and of a beautiful soft pink colour. A distinguishing feature of the whole plant, especially in winter when growth has matured, is the yellowish brown colour of its leaves; these are about 2ins. long and rather pointed, the undersides being but sparsely spotted with dull brown scales. Unfortunately, it is very scarce, being seldom seen, still less heard of, and very rarely if ever listed, neither do I remember having seen it in the Royal Botanic Gardens of Edinburgh, in spite of a close scrutiny of the many nooks and crannies of those wonderful northern gardens; but the overlooking of any particular

Digitized by Google

variety is even for an enthusiast quite a legitimate excuse when one remembers the vast hosts of rhododendrons that are to be seen there; nevertheless, its inclusion in any collection cannot be too highly commended.—J. T. HARRIS, *Wisley*.

SWEET-SCENTED CLIMBERS.

I AM now referring to hardy kinds, those so charming on our house and garden walls, pillars and pergolas. Roses are not included. How suitable for almost any position is Jasminum officinale, the tiny-flowered white variety, which is, practically, evergreen and may be planted in any exposed position, pruned and trained at will. It is most effective, in my opinion, when the shoots are allowed to hang gracefully from their supports and all attempts at formal training are abandoned. Clematis orientalis, also white flowered, makes very rapid growth and so covers much space in a short time. It is very suitable for a large wall or long pergola. Aristolochia Sipho is another rapid-growing climber bearing very strongly scented flowers. This plant, too, requires a lot of space in which to grow and show to the best advantage. Clematis Flammula, white, makes a fine covering for a large arch or a summer-house. Stauntonia latifolia is evergreen, bears fragrant greenish yellow flowers in spring; a distinct subject. Then there are the loniceras. Even the common one, Lonicera Periclymenum, is well worth growing in prominent positions. Lonicera belgica, early Dutch; L. serotina, late Dutch; Halleana (japonica) should be included. The honeysuckles are so valuable for rather shaded positions and where the soil is naturally dry. Usually, our climbers are planted in ordinary, poor soils. They will repay the trouble taken if they are afforded one bushel per plant of good fibrous loam.—HANTS.

CHRYSANTHEMUM SOURCE D'OR: AN OLD AND BEAUTIFUL SORT.

I HAVE very pleasant recollections of the introduction of this chrysanthemum, now many years ago. I first saw it at the Birmingham Society's Show in the Town Hall, and it appeared in the first prize pans along with Mme. Clemence Audiguier and other novelties of that—what seems to me—far-off time. Only Source d'Or has survived, and I notice in lists which reached me in November that it is included among "choice Japanese varieties for cut flowers and decoration." To what may we attribute the continued popularity of this worthy old sort, seeing that, so far as mere size of blooms is concerned, it has long since been superseded? To nothing less than its delightful colour, beautiful when it first opens in its orange-terra-cotta tints, and none the less attractive when it fades. I still grow it, and for general decorative purposes it is hard to beat. A good number of varieties, it is true, run it close as regards colour, but it stands alone. For home decoration it is worthy of note, as it carries its foliage well to the finish. If ever a variety earned a long service award, surely it is Source d'Or. It is still a profitable market sort by reason of its delightful colour. Some who grow it do so on the crown buds, but for home work—and this is its chief value to-day—it is more useful on terminals, and disbudded.—CLAREMONT.

CORRESPONDENCE

RHUS COTINOIDES.

SIR,—In THE GARDEN for November 14th, "E. C." states that Rhus cotinoides is not mentioned by Professor Sargent in the "Manual of Trees of North America," and if he will turn to page 657 of the Manual he will find it there described as a tree from 25ft. to 35ft. high and found very abundant as a small shrub spreading over many thousands of acres on the dry hillsides and mountain cañons near Spanish Pass in Kendall Co., Texas. Here, in the eastern states, it is extremely rare in cultivation.—WM. H. JUDD, *Arnold Arboretum*.

[This tree is given under the name of Cotinus americanus, which explains why I did not see it. Cotinus is a generic name that does not hold good in this country.—ED.]

DAFFODILS IN NEW ZEALAND.

SIR,—Our daffodil season has come and gone, and it has been the worst spring within the memory of the oldest inhabitant. Nevertheless, some very good flowers have been bloomed and shown, which is saying a great deal for the painstaking care of the growers.

Seedling raising in New Zealand has, with the exception of the late Mr. A. E. Lowe, not been gone into very fully by local growers until comparatively recently, and the fruits of the labours of those enthusiasts who took up the hobby some years ago are now becoming apparent. Last Saturday (October 3rd) I visited the gardens of a well known local amateur, Mr. C. Goodson of Hawera. In the last few years Mr. Goodson has raised some splendid varieties, *inter alia*, Wellington, a red-cupped incomparabilis, champion short-cupped daffodil, Wellington Show, 1924; and Goodson's Choice, a giant Leedsii, champion short-cupped daffodil at Wellington, 1925, beating well grown specimens of such well known varieties as Basilia, Silver Dawn and Tenedos. On this visit, however, I was astonished at the splendid even quality of his seedlings. He had dozens of varieties equalling, if not bettering, older standard varieties, and many of them fit to grace any show bench. However, on that day I saw what to me must be his masterpiece. It was a splendid Leedsii bloom. A fine upstanding plant about 24ins. high with a magnificent bloom; pure white, glistening perianth, flat and overlapping, with well shaped segments. Its cup was its main feature. It was well shaped and well frilled, and of a pure salmon pink right to the base. The whole flower measured some 5ins. across and the cup 1¼ins. in width and 2ins. in depth and, apart from its unique colour, it was of a shape and substance sufficient to satisfy the most particular. It appeared to me to be a complete break in colour, and after seeing it I could visualise all manner of beautiful coloured cups of which this may be the forerunner. The flower when seen by me had been out for nearly a fortnight, so its lasting quality is assured. As it was the first and only flower of this seedling tentatively named by the grower Queen Mary, its future will be watched, in this part at any rate, with keen interest.—ANDREW CHRYSTAL, *Eltham, N. Z.*

A MISTLETOE HINT.

SIR,—Many people when trying to establish mistletoe on an apple tree, put the berries in position round about Christmas-time. This plan nearly always results in failure, owing to the fact that the seeds are not ripe at this early period. As a matter of fact mistletoe berries do not reach ripeness until February. By far the best method is to select a well berried piece of the plant from the Christmas decorations and put this in a jar of water. Change the water every week and the mistletoe will keep fresh during the ripening of the berries. On a mild February day press a few of the berries on the underside of a healthy apple branch. One or two are almost sure to establish themselves and in due course the baby mistletoe plant will appear.—S. L. B. *Bournemouth*.

ON MOVING SHRUBS.

SIR,—The suggestion by a correspondent that something be written on this subject leads me to pen a few lines which I trust will be of some guidance to readers of what I consider the most up-to-date journal on horticulture, THE GARDEN.

My planting experience extends to well over thirty years and I can truly say I have had many ups and downs. This week I have been moving Laurus nobilis, 20ft. in height and weighing close on a ton each!

As the recent editorial on "The Disturbance of Plants" is mentioned, and more specifically a quotation, saying, ". . . to grow a rhododendron is to sow the seed in the exact place, etc.," I will commence with rhododendrons.

First, I do not think any large rhododendron grower would agree with Sir Isaac Bayley Balfour, one good reason being that such a practice is impossible. Further, such practice could only apply to species. All hybrids, of which we have so many, must be propagated either by cuttings, grafts or layers. Finally, I do not suppose Sir Isaac himself tried the experiment, as he mentions the word "theoretically."

Mr. Osgood McKenzie was, I consider, on the right track when he said, "Do not forget that rhododendrons like carriage exercise." As an illustration of this, I may mention many extra large bush and standard rhododendrons and azaleas which used (thirty years ago) to be replanted by the father of the present proprietor of the celebrated Knaphill Nursery. These plants were replanted each year in the springtime and those who remember their gorgeous display within three months of removal will understand that such transplantation did not harm them.

TRANSPLANTING.

Transplanting of trees and shrubs produces conditions of growth, fruitfulness, etc., which are favourable to the gardener.

Take a self-sown seedling of Rhododendron ponticum or Azalea japonica. If, during the first few years of their lives, they are not transplanted they will form but comparatively few feeding roots. They would grow tall and thin and the constant cutting to lick them into shape would only induce strong and sappy growths with little flower. On the other hand, if the seedlings are regularly shifted on, each time their roots are cut round a large number of *single* feeding roots are cut away, but within a very short space each cut root has sprouted and produced a *bunch* of new feeders. At the actual time of removal a great check is given to the supply of sap, for the moment its upward movement becomes stagnant and it ceases to function. But when the greatly increased number of feeding rootlets get into action, sap is again supplied in ever-increasing quantity, more than the present normal growth of the tree can deal with. Consequently, new buds are formed, long dormant buds are pushed into growth, often from near the base of bare and leggy plants, the whole plant benefits and becomes more bushy and free-flowering.

Digitized by Google

Most horticulturists will have noticed that Dame Nature always decrees that a plant has a means of reproducing itself. As an instance, this year I found a plant of charlock growing on a brick; it was less than an inch high, it had but two leaves, but it was flowering and probably set a seed or two. Its evident lack of root and nourishment had induced the plant to flower. This is the way with Nature, she will not be beaten. When a tree or plant is removed it is against Nature's law, she gets the wind up, she fears for her child. If the cruel gardener had not removed it, she would have had years in which to consider the reproduction of that particular tree. Now, alas! the gardener has cut its roots, it may die, she must hurry up, consequently she cannot pay so much attention to long, lanky growths, she (owing to the check of sap), produces short, fruit-bearing growths. This phase is often well illustrated by the well advised and timely removal or root-pruning of fruit trees.

Shortly, I am in favour of transplanting insomuch that if carefully carried out in all respects it does not harm the tree (excepting the violation of nature's law), but will actually add to its beauty, fruitfulness and, often subsequent growth.

Planting may be divided into two great classes. Class one, embracing evergreens: spring and autumn. Class two, embracing deciduous subjects, extending from autumn to spring.

To go into detail would occupy several numbers of THE GARDEN, but I will try to give a few ideas. Generally speaking, all evergreen subjects (and a good many deciduous ones) *must* carry a good and compact ball of soil on the roots. This, of course, includes all conifers.

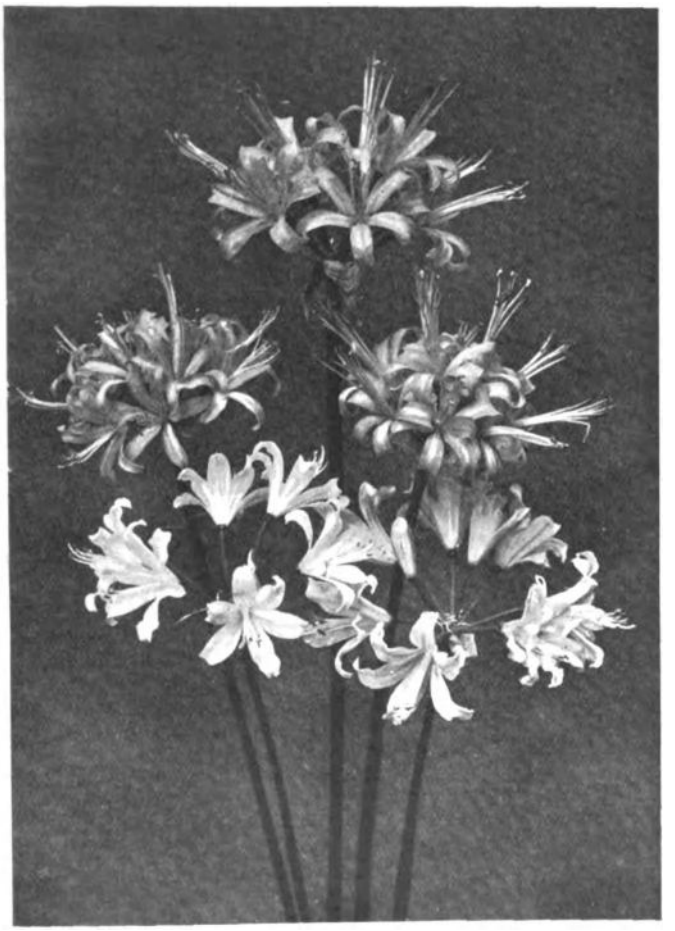
AUTUMN PLANTING.

Autumn planting may be commenced in late August, but at this time of year great care must be taken to get the soil nicely moist, as dry soil does not hold on in sufficiently large quantities to ensure a safe removal. Autumn planting (in cold districts) should be discontinued by the middle of October. In the very mild parts it can be carried out throughout the winter months. Spring planting may be commenced at quite the end of March and continued till the end of May, finishing up with the ilex.

Deciduous subjects may be planted with safety from the middle of October till the end of March, always provided that weather and ground conditions allow. The very important point raised, "good and bad moves," is a big one, almost too big to move with such a small tool as a pen. However, I will place rhododendrons and azaleas among the very easiest movers, followed by andromedas, ericas, cupressus, laurels, ilex, yew, box, aucubas, ligustrum and, in fact, all those subjects which form dense masses of root, as does the yew and box. Among less easily moved subjects are evergreen oaks, arbutus (if long standing in one position), pines, cedars, junipers, cytisus, gorse, ceanothus, senecios and olearias (if large trees), and many others. To overcome this, most nurserymen grow the more difficult subjects in pots. Nearly all deciduous subjects will transplant with safety, even up to a large size. By this I mean trees 30ft. to 40ft. in height and such as limes, chestnuts, ash, etc.

The more difficult deciduous trees, again, must carry a good ball of soil and such include magnolias, Japanese maples, oaks (some varieties), ilex (deciduous), Taxodium distichum, Ginkgo biloba, Citrus trifoliata, and a few others. I would point out that the difficulty with the foregoing is to plant them successfully *without* a good ball of soil; *with* a good ball they become as easy as the following, which may all be transplanted with little or no soil adhering to their roots. These include spiræas, deutzias, philadelphus, most viburnums, syringas, acers, alders, robinas, birch, ailanthus, paulownia, planes, rhus, prunus, cerasus, malus, cornus, perowskia, ribes, roses, tamarix, and very many others. Failures in planting may often be traced to such faults as, failure to water spring-planted trees, insufficient firming of soil about roots, allowing trees to rock in windy weather, planting too deeply, wrongly chosen sites, unsuitable soils, placing fresh manure on roots, careless lifting (by severing too many roots), failure to give shelter to tender subjects, planting in heavy soil without ensuring sufficient drainage, allowing grass and/or rank weeds to grow within the radius of the tree roots, mulching too heavily and/or at wrong time of the year, and planting when the ball of soil is very dry, planting out pot-bound subjects (these should be re-potted into pots some sizes larger several months before planting, so as to ensure a new root system). The foregoing are only a few of the many causes of failure—there are many others.

Finally, my advice to the inexperienced is, do not undertake the removal of very large trees or shrubs. Call in the nurseryman who understands such work. He will tell at a glance if the trees or shrubs can be moved with safety and will carry out the work far more cheaply, since he has all the required apparatus at hand.—JOHN HILL, *Paignton.*



THE FAIR BEAUTY OF HYBRID NERINES.

NERINES.

SIR,—With reference to the enquiry by "R. H." on page 707 of your issue for December 12th, 1925. In the great majority of cases nerines produce their flower-spike either slightly before or simultaneously with the foliage, the flower generally withering before the foliage has made any considerable growth. There are, however, certain late-flowering varieties which are exceptions to this rule. In particular, Nerine Manselli, a handsome tall and robust variety, bearing umbels of satiny rose cerise flowers, always produces its blooms at this time of the year, and will continue to do so in succession for several weeks yet, the foliage, in common with other varieties, being almost at its peak of growth. This peculiarity is shared by hybrids of this variety, and at the present moment several plants of Manselli, together with various hybrids of which it is a parent, are in flower, although the bulk of our collection has finished flowering for some considerable time. We also notice that certain hybrids of Nerine flexuosa seem to contain this late-flowering habit, and even flexuosa type frequently flowers after producing a certain amount of foliage.

We should say the recent flowering season for nerines has been quite satisfactory, in our experience better than 1924. We attribute this to the hot summer, which undoubtedly benefits these plants.—BARR AND SONS.

COLOUR VARIATION IN HYDRANGEAS.

SIR,—I was much interested in the letters on the above subject recently published in THE GARDEN. In a large garden near Southampton there were, some years ago, very large specimens of Hydrangea hortensis rosea, which bore huge heads of blue flowers, rivalling that of Gentiana acaulis, as referred to by Mr. Arthur J. Cobb in his letter. Some of the trusses of flowers were quite 18ins. across, yet, on the same plant a few heads of true rosea colour appeared every year. When these were cut out shoots from the same stems again produced the rose-coloured flowers. The plants grew in a shrubbery which was situated in a dry part of the garden. But on this estate, in almost boggy ground, some hydrangeas also bore blue and rose-coloured flowers. The water, running over pebbles or dripping on them from the garden taps—all the water in the garden was forced up from the ponds and springs—turned them almost red.

In a village near Bournemouth I have observed a row of Hydrangea hortensis, growing in front of a border well filled with the roots of large shrubs and trees, which always bears blue flowers and not a single rose-coloured bloom. The plants are never pruned back and so their branches and the flowers on them mostly hang down, some gracefully and others rest on the grass. There is iron in the soil and not any lime. The blue in this case, is always deep, like that of Gentiana acaulis. When trying to produce this colour in pot hydrangeas by using iron and alum, the colour has, generally, been of a very pale blue.—GEO. GARNER.

ORCHID NOTES FOR THE AMATEUR

ODONTIODAS.

WHEN the first odontioda was exhibited at the Temple Show of 1904 an immense amount of interest was created, for this little seedling plant indicated the extensive series that was soon to follow. At the above date the odontoglossums were at their highest point of popularity, and extraordinary prices were being paid for varieties having the segments marked with purple blotching. Consequently, the production of a flower with bright scarlet blotching was hailed with intense delight, for it opened up an entirely new scheme of coloration. This historic plant of 1904 was Odontioda Vuylstekeæ, the result of crossing Odontoglossum Pescatorei with Cochlioda Nœzliana, and one of the very few orchids to which the R.H.S. silver-gilt Lindley medal has been awarded.

Events have moved rapidly during the last twenty years, and more than 500 different odontiodas are now on record. This figure indicates the extensive additions which have been made in comparatively recent years to the cool-house section of orchids. For all practical purposes odontiodas may be treated similarly to the odontoglossums; in fact, these two genera have been so much intercrossed that it is frequently a matter of considerable difficulty to determine under which genus some of the seedlings should be recorded.

In no other section of the orchid family can so extensive a variation of colour be seen. From the bright scarlet of the Cochlioda Nœzliana parent to the deepest blood red, and from white and cream-coloured flowers to those of deep yellow, a long series of beautiful colour schemes can be obtained. The odontiodas add considerable beauty to that already existing in the cool house; they also greatly extend the season in which the flowers are at their best. Present-day amateurs can obtain a supply of odontoglossum and odiontioda flowers throughout every month of the year, whereas members of the past generation had them only in the springtime, and even with that short period they were fully satisfied.

The cultural details are similar to those previously described for odontoglossums. A moist atmosphere of between 50° and 60°, as cool as possible during the summertime, and not falling below 50° for any prolonged period in winter. These are conditions that exist in the majority of amateurs' greenhouses. One of the essential points in the cultivation of these plants is to prevent the foliage from being scorched by the sun, hence ample shading must be ready at an early period in the year. Blinds that can be removed daily are far preferable to any permanent shading, for the first and last few hours of sunlight are of great benefit towards creating a vigorous constitution.

CŒLOGYNE CRISTATA.

After Cypripedium insigne, no orchid is more easy to procure and cultivate than Cœlogyne cristata. Many an amateur who grows this plant will readily give away a few portions to anyone interested, and if this is done at the time of re-potting no apparent loss will result. Although discovered just over a century ago, there does not appear to be any record of this species having flowered in England until the spring of 1841. Its native home is in the lower Himalayan zone, at elevations ranging from 4,500ft. to 7,500ft., and even at higher and colder altitudes. In fact, Mr. Farrer and Mr. E. H. M. Cox found Cœlogyne cristata in Upper Burma smothering the branches of trees at an altitude of 10,800ft., where for four months of the year everything was covered with a mantle of snow. Yet, notwithstanding these severe conditions, the plants produced an abundance of snowy white flowers. What more suitable plant can be recommended for a greenhouse of comparatively low temperature?

If some orchids are uninteresting when not in flower, Cœlogyne cristata is always attractive, for its masses of bulbs piled up in pyramidal form, resemble a well filled dish of greengages. Generally speaking, this species does not flower well until the plant consists of numerous bulbs, oftentimes hundreds of them, so closely arranged that they rest one upon another. The plants will often continue for two or three years without requiring re-potting. But with all plants there comes a time sooner or later when re-potting is a necessity, and with this particular cœlogyne such operation affords a favourable opportunity for dividing the mass into smaller pieces and re-arranging them on a bed of newly prepared compost. Although small pieces of even three bulbs will grow and ultimately make moderate-sized plants, it is not advisable to split up an old specimen into quite such small pieces. Clumps consisting of a dozen or more bulbs are usually available, and if a few of these are arranged so that the new growths may have ample space to develop without reaching the margin of the pot, then healthy specimens will be produced. The usual clean fibre, into which a portion of sphagnum moss has been mixed, forms a suitable potting material. It is on record that a very small plant was grown on carefully year by year until it had a diameter at the base of over 6ft., and bore as many as 1,400 flowers, all open simultaneously. Such remarkable specimens are quite beyond the desire of the majority of amateurs, who could not afford sufficient room, but this example does show to what extent this plant can be cultivated, and its wonderful flowering capabilities.

The summer treatment of Cœlogyne cristata is of the easiest, a moist and shady position being its moderate requirements. It succeeds well in almost any temperature, and can be grown in vineries and along with many other greenhouse plants. At the conclusion of the growing season the water supply should be lessened, and only enough given to prevent the bulbs shrivelling. Care must also be taken that water does not lodge in the new growths, for damage may thereby be done. Although it has been mentioned that in its native locality this species is accustomed to comparatively low temperatures, it is not advisable to allow the thermometer to fall below 40° during the winter months. During the formation of the flower-spikes a higher temperature is necessary. It is also advisable to state that the flowers are very liable to become spotted through an excess of atmospheric moisture, especially during cold weather.

GURNEY WILSON.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

VEGETABLES

PARSLEY.

THIS is a very useful vegetable and always in demand more or less throughout the whole year. Yet to be successful in the growing of parsley it is necessary to trench and manure the ground thoroughly two or three months in advance of planting time. Seed takes a long time to germinate; sometimes a month elapses, when sown out of doors, before the seedlings show through the ground. The plants, too, are somewhat slow growing. It is rather a good practice to sow the seed in a box of medium fine soil very early in January, and bring the seedlings on under glass. As soon as they have made sufficient headway, they should be hardened off, then about the middle of April they should be set out a few inches apart in the open ground. When properly established and grown the plants will supply fine foliage from late summer till near the end of the year. Successional sowings should then be made out of doors from March, as requirements demand. Plants raised from early out of door sowings should be transplanted carefully into cold frames in September or early October to supply leaves throughout the latter part of winter and in the spring.

Parsley is a biennial plant, but is not quite hardy; therefore, if a supply is required in winter, etc., plants should be set out in frames as I have indicated, or the old plants in the open can be protected by having frame lights placed above them, which will keep off the rain and snow, etc. Plants, if not too severely defoliated when in the frames, can be lifted and set out early in April, 6ins. or 8ins. apart, in good rich soil. When once established they make excellent specimens, which provide a regular supply of large leaves, until they are cut down by severe weather.

It may interest readers to know that if plants are left without protection in severe wintry weather, their leaf-stalks get bleached and eventually decay. I have noticed that it is the leaf stalks which suffer first, thus indicating that they are not quite as hardy as the leaves. Three good varieties to grow are Champion Moss Curled, Methven's Green Gem and Myatt's Garnishing.—DAVID ARMSTRONG.

Digitized by Google

TO PREVENT "CLUBBING" IN CABBAGE AND CAULIFLOWER.

I NAME these two only, but all plants of the brassica family are subject to "clubbing." At one time it scared me very much; it does not now, nor has it for more than twenty years. Before that period I had thousands of plants fail year after year. The particular ground had to be cropped with these and winter greens, and had been so cropped for more than fifty years. When July came all early crops turned blue, and, in strong sunshine, their lower leaves lay on the soil. The same thing happened with later crops in September. Then the following year, as the ground became vacant, I applied 3 pecks of lime per rod, digging it in; later, before new plants were planted, a peck of salt per rod was forked in. Result: a wonderful improvement in the general growth and appearance of the various crops. Of course, the usual manuring was done. It took three years to eradicate this pest. Where ground is vacant in the autumn or about Christmastime, the liming is more effective if it can be applied then, spread on the surface of the newly dug soil. I advise all inexperienced cultivators troubled with this fungus to begin now to treat their soils, even those in which the seedlings are raised. The old-fashioned way of dipping the roots in a puddle of soil, soot and lime is sometimes scoffed at, but there is much virtue in it, especially so if a small quantity of paraffin emulsion is mixed with the mess. A wineglassful will be enough for a bucketful of the mixture, making the roots and their surroundings distasteful to the maggots also.—HANTS.

AN EARLY MAINCROP POTATO.

THE potato Norna, unfortunately, is not known so well as it ought to be. It is an early maincrop potato raised and introduced by the late Mr. Archibald Findlay, Auchtermuchty, Fife. It is a variety which is well suited for garden purposes; in fact, it should be everyone's potato, because it is a good cropper, of excellent quality, and gives a good account of itself on the exhibition table.

Norna has been proved resistant to wart disease, and can be grown in all gardens and allotments in Scotland. The tuber is flat and oblong, with very shallow eyes, skin and flesh white, very dry and of excellent quality. The growth is tall and upright in the early stage, but spreads out later in the season. The leaves are dark green and very glossy, secondary leaflets are prominent. The colour of the flower has, so far, not been observed, the dark green buds dropping without opening. The haulm and shape of tuber somewhat resemble Royal Kidney, and might be mistaken for that variety except that Royal Kidney is not so glossy and the haulm is very much more branched. Norna is immune from wart disease and fairly resistant to blight, while Royal Kidney is susceptible to both diseases.—GEO. STUART, *Edinburgh*.

SEEDS

SOWING FREESIAS.

I HAVE an idea that some of our big firms will be offering freesia seed in their seed catalogues. May I suggest to purchasers the advisability of steeping the seeds in water for twenty-four hours before they are sown? It will promote quick germination. I tried it last summer with some seeds a year old, and there was a very marked difference between these and those in a control pot where the seeds had not been soaked. This is, very likely, one of the little tips we would not think of in regard to freesias, although we practice it with other seeds.—JOSEPH JACOB.

COSMEAS.

WE have always found it advisable to sow the cosmea early in the year and to grow the seedlings in a frame until the weather is propitious for planting out. If that is done they will flower as soon as they settle down in the border and, as everyone knows, they will become larger and more prolific as the season advances. The singles are delightfully light and graceful, but the newer doubles are so much out of the usual run of things that they are even more attractive. These doubles are not quite fixed and 25 per cent. of the plants are sure to come single.—CLYDESDALE.

EARLY CYCLAMENS FROM SEED.

YOUNG cyclamen plants flower more satisfactorily than old ones possessing large corms. Usually the September-raised seedlings are the most profitable for amateurs, as they are robust and strong by mid-winter and grow rapidly in spring after re-potting. Such seedlings should be kept on shelves in a temperature of 50°, rising to 70° or a little higher from sun heat. When they are potted singly in small pots use a mixture of loam two-thirds, leaf-soil one-third and coarse silver sand to ensure porosity. Keep the tiny corms just level with the soil in the pot and preserve every root at this stage, as even the healthiest seedlings possess but a few. Apply water from a tank in the same house, and be sure that afterwards water is not applied injudiciously. A second batch of seedlings should be raised from seeds sown about the middle of January. Although the plants flower within the year if properly treated, the seeds require a long time in

SEASON 1926

VEGETABLES OF QUALITY

THE painstaking care in Selecting, Testing, and Raising only the best varieties of Vegetables is again confirmed in the record list of Gold Medals awarded during 1925 to Exhibits of Carters Vegetables.

It is well to remind our Customers that over 12,000 individual test rows were grown to full maturity in our grounds at Raynes Park during the past season, to compare and examine the merits of each variety at every stage of growth.

This process is carried out each year so that the highest standard of quality is maintained.

We respectfully invite you to inspect our processes by paying us a visit at Raynes Park.

which to garminate. and they germinate irregularly, so it is a wise course to retain the seed-pan intact for several weeks after the first seedling is well developed. A similar, kind of compost is suitable for the seedlings as for the potting of the young plants, only it should be finer. When the resultant seedlings possess two leaves they should, from a January sowing, be transplanted round the sides of large pots or pans prior to being potted singly. So treated the tiny plants will form roots more freely than if they were in soil in the centre of the pot.—CHRISTCHURCH.

MISCELLANEOUS

SAND: ITS USE AND ABUSE.

I DARESAY sand is as commonly used in the garden as any ingredient for the benefit of the roots of plants. It is often included in composts when the latter would be of more value without it. Sometimes sand is omitted when its presence in a compost would undoubtedly do a lot of good. A very small quantity can rarely do harm, but an undue proportion in a tiny pot will not benefit the plant proportionally. If a grain of sand is placed under a powerful glass it will be seen to resemble quite a big piece of rock—if wet, similar to a small boulder by the seaside. We often make use of the expression "as dry as sand." It is when sand, in undue proportion, is allowed to get practically dust-dry that the roots of plants in it may soon suffer. I have seen thousands of cuttings in such sand suddenly wilt and never again recover normal conditions. So we ought to consider the matter closely when we are about to use sand, and not to add too much of it to any compost. Its beneficial use is to keep a soil mixture open so that water and air can pass through it and also to conserve moisture for the benefit of the roots. For these reasons we use sand in a clean state for propagation purposes as well as in potting composts. But there are many kinds of plants which like lime, and in their case especially it is more beneficial to substitute old mortar rubble for sand. A few kinds are fuchsias, primulas, ferns and chrysanthemums.—HANTS.

THE DRAINAGE OF LAWNS.

PROBABLY there are many readers of THE GARDEN who have had trouble with their lawns or tennis courts during a rainy spell of weather just when they particularly wished to use them. The present is a suitable time to rectify matters of this kind. Other readers are, no doubt, intending to form new lawns either by turf-laying or seed sowing next March or April. If the ground is naturally wet in ordinary seasons, some drainage is absolutely necessary. If the work is done now, the disturbed soil has time to settle down firmly before the grass seeds are sown. To help matters in this direction, water the soil as it is being replaced in the drain trench. Begin the refilling at one end and fill the trench to the top as the work proceeds, then the soil will fall evenly on the pipes and both sides of them keeping them in position. By dropping a small quantity of soil on the pipes their whole length, some of them may be displaced. It is possible in some cases to make a wet lawn fairly dry by forming a drain at the lowest side or end, quite on its edge, as such drains will draw off a lot of water. Tennis courts may be dealt with in this way in some instances, then the actual playing ground is not disturbed. A good average depth for a drain is 30ins. in ordinary soils, 2ft. in very clayey ones.—GEORGE GARNER.

CATALOGUES RECEIVED.

Seed catalogues now continue to arrive almost daily and those which we have to record are Messrs. Suttons and Sons of Reading, Messrs. Webbs of Stourbridge and Messrs. Alex. Dickson and Sons, Limited, of Belfast. Messrs. Suttons have again excelled all their previous efforts in the production of the excellent manual which appears for 1926. It is comprehensive in its scope, dealing adequately with the flower garden and its inmates, as well as with the utility garden. The descriptive and well classified lists will prove of the greatest assistance to those who are pondering deeply over what to select. Turf and its upkeep comes in for its fair share of attention and many helpful hints are given in these pages. The catalogue is a worthy successor to its predecessors. It is well and clearly printed and profusely illustrated by means of numerous excellent half-tone reproductions. The illustrations in themselves are exceedingly helpful. It is a manual which all gardeners—amateur and professional—should obtain in order that they may become thoroughly acquainted with the latest things in the world of horticulture. Messrs. Webbs' catalogue, also holds much of interest, especially in the vegetable section. The subject matter is well illustrated and numerous cultural hints and notes are given throughout its pages. The descriptive lists of flower seeds extend over about forty pages, and the text, together with the many excellent half-tone reproductions, should prove of the greatest assistance and interest to all gardening enthusiasts. Messrs. Dicksons need no introduction to readers of THE GARDEN. Their "Hawlmark" seeds are known throughout the length and breadth of the land. This year they have published a very attractive catalogue in which the special feature is an article by Mr. E. T. Dickson on Sweet Pea Culture. This is an admirable guide to to all intending growers of sweet peas during the coming season and one which they will find of the greatest use. The numerous descriptive lists offer a wide selection both in flowers and vegetables.

Messrs. Richard Melhuish, Limited, Fetter Lane, Holborn, E.C.4. A most comprehensive catalogue of woodworkers' tools and machines. Although this brochure does not deal with ordinary gardening tools, still there are many articles in it of use to the gardener, such as special saws and axes. There are 1,100 illustrations in line, and the price of the catalogue is 2s. post free, returnable on the first order of 10s.

Mr. H. J. Jones, Ryecroft Nurseries, Lewisham, S.E.13. List of hardy plants, including a fine selection of chrysanthemums, Michaelmas daisies, phloxes and hydrangeas.

Messrs. Austin and McAslan, Glasgow.—Catalogue of trees and shrubs, including fruit trees and conifers. Also a list of alpine and herbaceous plants suitable for planting now.

Messrs. Harrison and Sons, Leicester. Novelties and specialities in the vegetable world for 1926.

Messrs. Barr and Sons, 11, King Street, Covent Garden, London.—A list of surplus stock of winter and spring flowering bulbs at greatly reduced prices. Also a special clearance offer of surplus perennials, alpines, ornamental shrubs and hardy climbers to be sold for cash.

FOREIGN.

M. Herb, Via Trivio, 24–36, Naples, Italy. Wholesale catalogue of seeds.

Messrs. Sire-Pernet, Lyon-Monplaisir. List of roses for 1926.

From Paris we have received Messrs. Vilmorin-Andrieux et Cie's catalogue of seeds of trees and shrubs. There are many interesting items and all shrub lovers should obtain a copy for reference purposes.

BARR'S CHOICE FLOWER SEEDS

A FEW NOVELTIES AND SPECIALITIES FOR 1926.

	Per pkt. s. d.
ANCHUSA Italica Lissadell, a beautiful border plant producing large flowers of a clear Gentian blue, h.p., 5ft. 1s. &	1 6
ANEMONE ST. BRIGID, Barr's "Glory" Strain, a very lovely and refined strain, bred only from selected vermilions, scarlets, roses and pinks. In flower beds and borders this beautiful strain will be much appreciated and the flowers greatly prized for cutting, h.p., 1ft. 1s. 6d. &	2 6
ANTIRRHINUM, mixture of glowing orange-scarlet and scarlet shades, a blend of the finest varieties of these colours, giving a most glorious fiery effect in the garden, 1½ft. 6d. &	1 0
AQUILEGIA, Barr's New Rose and Scarlet Shades, extra selected strain, very beautiful large flowers, mostly with long spurs, colours rose-scarlet and rose to amaranth-pink with white or yellow corolla, h.p., 2ft. 1s. 6d. &	2 6
AQUILEGIA Rose Queen (new), a beautiful long-spurred large-flowered variety of a lovely rose shaded white, h.p., 2ft. 1s. 6d. &	2 6
AUBRIETIA, Newest Hybrids, Mixed, a wonderfully fine strain, producing a good range of colours, from deep purple, blue and lavender to blush, pink, rose, carmine and crimson, all large-flowered; lovely on rockwork, h.p., ¼ft. &	2 6
AUBRIETIA Whitewell Gem, flowers large, rich violet with white central halo, very effective, ¼ft. 1s. 6d. &	2 6
CAMPANULA Telham Beauty, a grand variety of C. PERSICIFOLIA, introduced by us, and given the R.H.S. AWARD OF MERIT. Produces on long stems immense bell-shaped open flowers, beautiful clear lavender-blue, h.p. 4ft. 2s. 6d. &	3 6
CENTAUREA Cyanus Double "Silver Queen," a very beautiful double white CORNFLOWER which will be highly appreciated for cutting; h.a., 2ft. For this variety we were given an AWARD OF MERIT, R.H.S., 1922 6d. &	1 0
CYNOGLOSSUM Blue Gem, an improved type of the Chinese C. AMABILE, producing large sprays of brilliant blue Forget-me-not-like flowers in early summer; a fine border plant, h.b., 1½ft.	1 6
DELPHINIUM Taplow Blue, producing long spikes of large open single flowers, Cambridge-blue shot rose-pink with conspicuous white centre, of graceful branching habit, h.p., 7ft.	2 6
DIGITALIS (Foxglove) "The Shirley," a magnificent new strain raised by the late Rev. W. Wilks; it produces plants 5ft. to 7ft. high, with spikes 4ft. long, carrying flowers of great size ranging from white to dark rose, handsomely blotched and spotted crimson, maroon and chocolate, h.p. 1s. &	2 6
GENTIANA Farreri, a very beautiful and rare species from China, of semi-prostrate growth, producing, in August, large sky-blue flowers with white throat, and veined black	3 6
LILIUM auratum platyphyllum, a grand border Lily producing immense flowers, with broad white petals, spotted crimson	2 6
LILIUM martagon album, a very beautiful Lily bearing pyramidal spikes of wax-like pure white flowers	1 0
LILIUM martagon dalmaticum, a stately Lily producing spikes of glossy dark rosy maroon flowers with reflexed petals	2 6
LILIUM Regale, a very beautiful Chinese Lily bearing large trumpet-shaped fragrant flowers, white flushed yellow, with ruby red on back of petals, hardy bulb, 3ft. to 5ft. Flowers in two years from seed	2 6
LUPINUS Cross Roads (syn. PEARL ROSE) **(new),** very beautiful bold spikes of large flowers of a beautiful soft flesh colour, lasting long in condition, of good habit, 3ft. 1s. 6d. &	2 6
LUPINUS Eastern Queen (syn. EVENING GLOW), producing from May to August long spikes of beautiful flowers, opening mauve and yellow and passing to rosy buff and fawn, 4ft.	1 6
LUPINUS Taplow Yellow (new), producing long sprays of clear yellow flowers, 4ft. **The finest yellow Lupin yet raised.**	1 0
MECONOPSIS integrifolia maxima, early-flowering form, a grand new form of the **Giant Yellow Poppy from Tibet,** forming a handsome rosette of foliage, from which rises a bold stem carrying up to thirty large and beautiful lemon-yellow flowers about three times the size of the typical M. INTEGRIFOLIA, April-flowering, h.b., 2½ft. to 3ft. 1s. 6d. &	2 6
MYOSOTIS, Barr's Alpine Blue, the richest blue of all FORGET-ME-NOTS, forming compact bushes literally covered with heads of lovely intense deep blue flowers, producing a striking effect in flower or rock garden, h.p., 9ins. 1s. &	1 6
PANSY, Choice Fancy Strain, a beautiful strain of fancy-coloured Pansies in the greatest variety of colour and markings, including reds, browns, bronzes, purples, etc., some beautifully margined, flowers large, ½ft.	1 6
PAPAVER Burseri, a rare alpine with large crystal-white flowers of sweet fragrance, hardy alpine biennial, ½ft.	2 6
PAPAVER nudicaule "Pearls of Dawn," a most lovely new strain of ICELAND POPPIES, satiny flowers of beautiful delicate shades, h.b., 1ft. 1s. &	1 6
POPPY, New Double Queen Poppies, a lovely new strain of the Shirley type, flowers double and semi-double, of delicate and brilliant colours, 2ft.; valuable for cutting, h.a.	1 0
PRIMROSE, Barr's Selected Blue, from the best lavender and blue shades	2 6
ROMNEYA trichocalyx, an improvement on R. COULTERI (the giant white bush Poppy of California), being a free bloomer and bearing very large snowy white flowers, with golden stamens, h.p., 4ft.	2 6
SCHIZANTHUS Wisetonensis, Barr's Giant Prize Strain, a grand strain having graceful Fern-like foliage and bearing a profusion of large flowers all with handsome markings mostly on light-coloured grounds, but a few on rich blue and purple grounds, h.h.a., 1½ft. 1s. &	1 6
STOCK Empress Elizabeth, a fine **Giant Brompton Stock,** forming handsome pyramidal heads of large and beautiful flowers of a brilliant bright rose: a grand pot plant, 15ins. About 75 per cent. of the seedlings generally come double 1s. &	2 6

WAKELEY'S *Celebrated* Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

A BEAUTIFUL FREE BOOKLET giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2.6 per bag.

This is ***THE*** *SCIENTIFIC WORK ON GARDENING.*

THE GARDENER'S ASSISTANT

EDITED BY WM. WATSON, F.R.HORT.S.

The prejudice against so-called scientific works is their highly technical language. When reading or studying the "GARDENER'S ASSISTANT" it is not necessary to have a Dictionary or Encyclopædia at your elbow. THE BOOK IS WRITTEN IN PLAIN EVERYDAY LANGUAGE and the information is clear, concise, and on unimpeachable authority.

THE BOOK WITH A GREAT REPUTATION.

The Knowledge of the Great Botanic Gardens, KEW, EDINBURGH, CAMBRIDGE, is at your service.

THE GARDENER'S ENCYCLOPÆDIA.

THIS, the most important book on gardening ever published, has just been completed under the direction of WM. WATSON, F.R.Hort.S., Curator of Kew Gardens, assisted by 22 specialists—each an expert on the subject he writes upon. From its pages the expert and amateur alike

HOW to cope with and overcome the difficulties, small and great, which frequently trouble the small gardener. **WILL LEARN** **HOW** to get the best value from his investment of Money, Time, and Effort.

Each branch of horticulture and its allied subjects has a definite section of its own, and each section is correlated by cross-reference wherever needful. There are hundreds of text illustrations in addition to a magnificent series of full-page coloured plates.

Science is the keynote of successful horticulture, and science discloses most of her treasures to all who can use the key of specialised knowledge. The new edition of the "GARDENER'S ASSISTANT" is as great a boon to the present-day gardeners as the early editions of this historic work were to the generations who built the great tradition of British Gardening. It is a veritable UNIVERSITY OF HORTICULTURAL LORE, an ENCYCLOPÆDIA of every process, every problem, every plant to which gardeners, market gardeners, fruit growers, bulb growers, nurserymen, garden architects and landscape gardeners, seed growers and merchants, hybridists and specialists are called upon to apply their skill and knowledge.

The new "GARDENER'S ASSISTANT" thoroughly justifies its claim to be a work of deep interest and importance to everyone connected, professionally or as an amateur, with gardening.

READ WHAT YOUR PAPER SAYS:

"It appeals to all who garden, professional or amateur. The former will find it of the greatest possible use in supplying a ready and satisfactory answer to all those detailed questions which crop up with marked persistency in the carrying out of gardening duties.

"To the amateur, it comes, like the Waverley pen, as a boon and a blessing."

—THE GARDEN, *December 5th*, 1925.

Brief Synopsis of Contents.

The Fruit and Vegetable Garden.
Kitchen Garden Vegetables.

Index, etc., etc.

Some Recent Testimonials.

Redruth, 28/12/25.
One cannot fail to strongly recommend the books to any garden lover, professional or otherwise. I have seen nothing yet to approach them for definite instruction and description.
(Signed) H. E. T.

Lancaster, 14/10/25.
From a brief survey I have had of them, I find them to be all that you claim. They are a valuable asset to any gardener, and especially so to a young man serving his apprenticeship, or to anyone who, put into a position of responsibility, comes across something he has had little experience of. (Signed) T. G.

Crewe, 19/12/25.
I have examined the work and am very pleased with the information it contains—it is a work I have been wanting to get hold of for a long time. (Signed) A. H.

Eldon, Durham, 29/11/25.
I find them very useful books for all interested in any class of gardening. I have had a life's experience of general gardening, nursery and green-keeping, and yet the wide range of subjects dealt with in this work will be a great help to the most experienced, as well as amateurs.
(Signed) D. W.

THE WORK IS NOW READY—COMPLETE IN SIX HANDSOME VOLUMES.

PRESS OPINIONS.

The work is one that should find a place on every gardener's bookshelf, to be "read, marked, learned and inwardly digested."—GARDEN LIFE.

The "GARDENER'S ASSISTANT"—like Goldsmith's immortal schoolmaster—"allures to brighter worlds and leads the way."—GARDENERS' CHRONICLE.

It is unnecessary for us to recommend the work to garden-lovers, amateur or professional. They know it already.—GLASGOW HERALD.

If is the gardeners' whole library in six complete volumes, a work which no gardener, amateur or professional, can dispense with.—LIVERPOOL COURIER.

SUTTON'S GARDEN PEAS

"Quality Tells"

There are no Peas to surpass our well known strains either for reliability, appearance, or for table quality, and Sutton's Garden Peas are far cheaper in the end than the "cheapest" seed you can buy.

To assist customers in obtaining a succession of *delicious Peas from May to November* we offer the following collection consisting of some of our best varieties specially selected for this purpose.

Sutton's Pioneer.
Sutton's Early Giant.
Sutton's Selected Duke of Albany.
Sutton's Prizewinner.
Sutton's Peerless.
Sutton's Eureka.
Sutton's Perfection.
Sutton's Late Queen
or other choice varieties.

REMARKS ON ANNUALS

MY editorial in the seed number is, I feel, rather an encumbrance and for several reasons. For one thing annuals are such an important item in our gardens and the catalogues produced nowadays are so imposing and such works of art, that I dare not pin myself down to a description of my likes or dislikes; besides I am not sure that I have any violent dislikes in annuals, whether flower or vegetable, except parsnips, which I cannot abide. The vegetables are so useful and the flowers lead such a short, happy life, that it seems a pity to show preference among living things that are here to-day and gone to-morrow, leaving behind them a trail of pleasant memories. This is, perhaps, a vague statement, but annuals are fleeting things and where unpleasant and clashing sights are seen, they are usually due to defective colour combinations. In the following pages will be found warnings against haphazard sowing and these warnings should be taken to heart.

A certain number of gardeners cannot be bothered with annuals, perhaps owing to their imagination or thoughts running back to the stilted days of formal bedding, but if the question was put to the vote, I should wager that most people would place annuals as the most useful group of flowers in the garden.

They can be put to such a diversity of uses. Borders made up solely of annuals, in the greenhouse, for beds, for filling up blanks in the herbaceous border or rock garden, for covering odd corners, that would otherwise lie bare, with a temporary riot of colour; they are the plants for the very young and the very old, although I find that, contrariwise, the older a garden enthusiast gets the more he likes trees and shrubs, the slower growing the better. Children, however, should always be taught to take an interest in annuals, for their patience has not time to run out before they see the result. Personally, I have promised myself a plethora of annuals if I live to sixty and am lucky enough still to possess a garden, although I expect that I will follow the general run and become passionately devoted to some tree like the oak. Elderly people have an admirably complacent and patient outlook on life that is as well shown in gardening as anywhere.

May I, in passing, compliment the seedsmen upon their excellent naming of varieties? Their names are usually to the point and have not the exasperating habit of arousing the curiosity of the purchaser. Am I extra inquisitive or is it normal to have an intense desire to know who and what were such ladies as Maggie Mott and Mrs. Bradshaw? The plants give no clue; but I should imagine many gardeners would be glad to know who gave their names to a viola and a geum that are such universal favourites that Maggie Mott and Mrs. Bradshaw will go down to posterity, unknown except for these two plants, unless I am doing them an injustice. I suggest that raisers should always say who the individuals are after whom they name their plants. Needless to say I do not refer to those which have the raiser's name attached, such as Barr's Pink Michaelmas Daisy or Sharpe's Express potato.

Seedsmen, on the other hand, often name their strains very happily, so that the names do give some idea of the plant. For instance, no one could find a better name for an aquilegia than "White Wings," a poetical fancy, but entirely descriptive at the same time. Cyclamen White Swan is another example, so is the Fawn, a terra-cotta and pale yellow antirrhinum. I could quote hundreds of examples of such pleasant and useful names, which, I contend, are infinitely preferable to the names of individuals, however worthy they may be.

E. H. M. C.

KEW GARDENS ADMISSION FEE.

The Ministry of Agriculture and Fisheries has decided to re-impose, as from January 1st, the admission fee of one penny—on other than Students' days—to the Royal Botanic Gardens, Kew, which was abolished in April, 1924, and which previously yielded a revenue of about £5,000 per annum. The present admission fee of 6d. on Students' days (Tuesdays and Fridays) will continue to be charged.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

PERENNIALS FROM SEED, by J. L. Gibson.

ANNUALS FOR HANGING BASKETS.

WINTER-FLOWERING BEGONIAS, by T. W. Briscoe.

PLEASE REMEMBER TO TELL OTHERS ABOUT YOUR PLANTS THROUGH THE COLUMNS OF "THE GARDEN."

THE FLOWER SEED ORDER

NOW IS THE TIME TO MAKE OUT YOUR SEED ORDER FOR 1926

WHAT shall be the method of procedure? Shall it be to start at A, and take the catalogue page by page in alphabetical order? There are objections to this, for it usually means a very close scrutiny of the first few pages, with a tendency to book a packet of every attractively described item, and by the time the letter "M" is reached a tiny doubt arises as to whether accommodation will be equal to the whole range of seeds on the list, which is assuming great length. Then begins an attempt at more rigid discrimination, and before the last few pages are reached it is decided that there simply cannot be room in the garden for any more seeds. That would be satisfactory if all the best of species and varieties of flowers were grouped in the earlier pages of the catalogue, but that, of course, is by no means the case.

The better plan is, first, to make a rough draft of "indispensables," which will be those seeds which are required for specific purposes, such as carrying out a bedding scheme, providing flowers for cutting, plants for the greenhouse, and the climbers for screens or trellis-work. Next, let us carefully peruse the catalogue in search of desirable additions to the herbaceous border or rockery, and for a few novelties or out-of-the-way plants that have not before been tried—for every season should witness some change, some addition and improvement, something experimental in the programme of the garden.

With the rough draft before one it is possible to gauge the relative quantities of seeds that will be required or that can be accommodated; and then will come the final selection of varieties and the copying of the list in its proper sequence, for which purpose the best catalogues provide a printed order sheet.

Selection of varieties is of equal importance to choice of subjects, and while there is a certain amount of prudence in remaining faithful to old favourites because they have always done very well, there is a lack of enterprise in making this a confirmed habit which will prevent a garden reaching the highest standard of excellence to which it might attain.

We need go no farther than annuals to point out that what was best a decade back, or even less, is very far from best to-day, and although seeds of the latest developments and purest stocks are naturally more expensive than the common herd, the difference in price of the best seed and the other is, after all, so small as to be beneath reckoning as compared with the difference in the joy they give.

For example, in viscarias, which erstwhile were dainty flowers of elegant grace, frequently spoilt by a sprinkling of flat, dull colours and a certain number of unruly straggling plants, we have now choice strains of wonderfully even growth and clear, distinctive and fixed colours. So great has been the improvement in the best strains that viscarias should, instead of remaining an oddment, occasionally seen in some large garden, become a prominent feature in all gardens of refinement.

Both nemesias and schizanthus were, until recent years, invariably grown in mixture, and, while the colour range in both subjects is admittedly extraordinarily fine, there are many people who dislike bizarre effects, and many situations and environments where distinctive, individual colours are unquestionably more appropriate. Schizanthus roseus compactus, for instance, is an exquisite flower, and the plant is so beautifully symmetrical and compact that it makes an ideal bedding plant. So thoroughly well selected for the purpose has it, in fact, been, that the best stocks, even when grown for seed, are more successful in the open than when grown in pots under glass. Nemesia Blue Gem is a marvellously refined stock, blue as a forget-me-not and as even in growth as a lobelia.

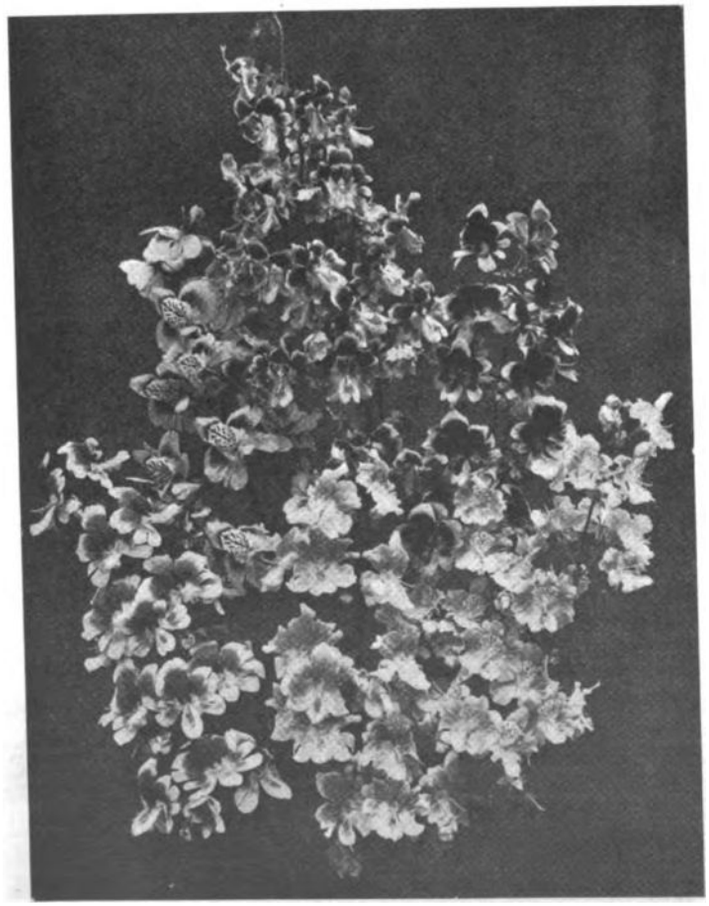
Wonderful improvements have been made in clarkias, and one may have a beautiful clear pink by ordering Dorothy, a deeper rose in Rosy Morn, an intense salmon shaded orange in Orange King, or a veritable blaze of fire with a bed of Brilliant. Godetia Crimson Glow is a bedder *par excellence*; its colour can never be adequately described in print, for the "glow" is something which suggests a silent communion between the flower and the sun which we mortals cannot understand, but can only look upon with wonder. The plant, too, is so beautifully compact, and blooms with a freedom which is marvellous.

Totally distinct in character, but certain to become widely popular, is the azalea-flowered godetia. Its blossoms are of immense size, with broad guard petals and centres with zones and blotches of contrasting colours which certainly convey an impression of mimicry of the glorious Indian azaleas.

Petunias are among the seeds which require an early start to ensure the finest results, and in few flowers has more striking progress been made than in the latest developments of this genus. The developments divide themselves in two or three different directions, but one of the most serviceable breeds is a group of smooth, circular trumpet-flowered bedders of wonderfully compact habit and freest flowering propensities. Rose of Heaven is a perfectly clear self rose-pink. Rosy Morn is of deeper carmine shade. Red Ray is fiery crimson with a large five-pointed star of pure white in the centre of each flower; and Red Violet is of a shining wine red, with a sheen of black and a perfectly white centre. There is also an absolutely pure white variety named Snow Queen. Of totally distinct character is the single "superbissima" strain which, although of very dwarf habit, produces truly enormous flowers which are heavily frilled—almost parsley curled, in fact—at the edges, and the throats of which are fantastically netted in a manner that reminds one of the beautiful pencilling of the salpiglossis and the netting of Iris Susiana.

These single giant-flowered petunias have their equals in circumference of flowers in the double "peony-flowered" petunias, which are alike suitable for outdoor bedding or for pot culture.

Mention of salpiglossis brings to mind the fact that there are some quite remarkable new selections and strains of salpiglossis, some being line-bred to an extent which ensures about 80 per cent. true to a uniform colouring, others of neat, dwarf



THE SCHIZANTHUS WITH ITS WIDE RANGE OF COLOUR IS A MOST EFFECTIVE SUBJECT FOR THE COOL HOUSE.

Digitized by Google

and very compact habit, others again which will grow 4ft. high and throw out great arms to make a spread equal to the height, with blooms of appropriately large size and of colour combinations found in no other flower within our ken. It is passing strange that a garden should be found which contains no salpiglossis. If their culture demanded great skill, and the nursing temperature of a tropical plant house, we should rave about their unique charms and millionaires would vie with each other to possess the finest collections.

For ages the Scottish florists grew calendulas (Scotch marigold) and found them so free, so accommodating and so effective that they became ubiquitous. Alas! familiarity breeds contempt, and because the labourer and artisan grew them marigolds became somewhat despised and neglected. It took an American commercial grower to show us our folly, by making money simultaneously with the task of opening our eyes. Ball's Calendula is grown in huge quantities to-day; but we also have produced some wonderful varieties, and Monarch, or a select strain of Orange King or Prince of Orange, will throw the glory of sunshine into the dullest garden.

Stocks are everybody's favourites, and when raising seedlings it is just as easy to raise a fine strain, such as The Dreadnought or Beauty strain, as to be content with nondescript inferiority.

In asters, too, the best of the Ostrich Plume and glorified Comets are no more trouble than the common run of penny packet lines: but what an enormous difference in the flowers produced! There is truly no sound reason for contentment with mediocrity.

Even so homely a flower as the nasturtium is to-day an educated aristocrat compared with the ruffian of yore, if only one will take care to order from a good firm improved stocks of Tom Thumb Scarlet, Crimson, Yellow or White, or such named varieties as Golden King, Shining Morn, Feltham Scarlet, etc.

The pages of THE GARDEN would need expansion to hold the briefest of notes of all the annuals of which I fain would write; but let me urge the reader who desires calliopsis to sow The Garnet and Flamingo; to secure, in readiness for outdoor sowing, eschscholtzias Winsome, Enchantress and the latest improvements upon Mikado; and let none overlook the exquisite double Shirley poppies, of which several fine strains are now available.

Lavatera Sunset is a gem, and, wherever a dwarf continuous plant of real pure blue is required, Cynoglossum amabile will amply fill the need.

The huge dahlia-flowered zinnias are worthy of a column article to themselves; and how much could be written upon annuals for the greenhouse: the celosias, Statice Suworowi, gorgeous mimulus, impatiens, balsams, and that marvellously graceful plant Humea elegans. Despairing, however, of cramming all into one short article, I turn from the greenhouse to make a brief but urgent appeal to all who want the most dazzling blaze of scarlet imaginable to sow early a batch of Salvia Harbinger, potting the seedlings on without a check, and in due time hardening off in readiness for planting out in May.

REMEMBER THE DECORATIVE VALUE OF SHIRLEY POPPIES.

CLUMPS OF GODETIAS BY THE PATHSIDE.

The modern spiral candytufts in white, and clear, distinct pink, red, maroon and purple varieties are of serviceable character, and the best strains of sweet scabious in selected shades of colour, provide elegant decorative material for vases, while the plants are equally adapted for filling gaps in the herbaceous border or for massing in beds by themselves.

Gilia coronopifolia is an annual of quite distinctive charm, that should be sown early, under glass, potted and planted out when well hardened. Several strains of hybrids, embracing other colours than the typical scarlet are available. Verbenas, remarkable for intensity of colouring, should also be sown at once, potting the seedlings and pinching their points to induce early branching.

Remember the importance of the climbers. Cobæa scandens, Eccremocarpus scaber and Mina lobata should be among the earliest seeds sown; while that good old favourite Tropæolum canariensis may be held back another month. A. J. MACSELF.

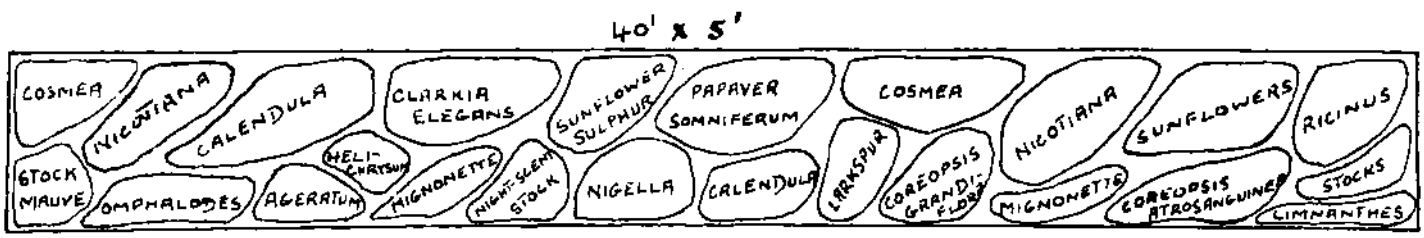
THE ANNUAL BORDER

ANNUALS possess three outstanding characteristics. They are cheap they are easy to grow, and, if well chosen, they supply clear bright colour in the garden. This combination of good things should prove irresistible to garden lovers, yet a border set apart for annuals is rare. Spaces in herbaceous borders, odd corners and bare patches of seeds. Colour, height, manner of growth and flowering-time are all important points. Height is particularly important, sudden jumps from dwarf plants 4ins. high to plants of 2ft. or more being ugly and unnecessary. If a brief but glorious blaze of colour is wanted, annuals which flower simultaneously must be chosen, but it is more usual sympathetically, and do not water unless the season demands this with a loud voice, in which case water thoroughly with a very fine spray. The illustration shows a specimen plan for an annual border containing both hardy and half-hardy flowers. A list of the flowers suitable for this border is given below: Ageratum mexicanum, half-hardy; Calendula



officinalis (marigold), hardy; Coreopsis grandiflora, half-hardy; Coreopsis tinctoria, hardy; C. t. atrosanguinea, hardy; Cosmea bipinnatus, half-hardy; Delphinium Ajacis (larkspur), hardy; D. Consolida, hardy; Helichrysum bracteatum (everlasting flower), half-hardy; Limnanthes Douglasii, hardy; Nicotiana affinis (tobacco plant), hardy; Nigella Damascena (love-in-a-mist), hardy; Omphalodes linifolia (Venus' navelwort), hardy; Matthiola (stock ten-week), half-hardy; M. bicornis (night-flowering stock), hardy; Papaver Somniferum (opium poppy), hardy; reseda (mignonette), hardy; Ricinus communis (castor-oil plant), half-hardy; and sunflowers—small varieties—hardy.

A short list of other good annuals: Centaurea Cyanus (cornflower), hardy; C. moschata (sweet sultan), hardy; Clarkia elegans (Salmon Queen, double); Eschscholtzia californica, hardy; Lathyrus odoratus (sweet pea), hardy; Linum grandiflorum (flax), hardy; and tropæolum (nasturtium), hardy.

are all filled with annuals, but the full glory of an annual border is seldom seen. Given the desire to make much of annuals, certain requirements must be fulfilled. A sunny position should be chosen for the border, which must be neither too wide nor too long; excessive width leads to thin effects, while too much length may produce monotony. The soil should be light, rich and well prepared; a good manuring every other year gives the right degree of richness. The final requirement is a plan. Because the colours of annuals are bright and sometimes crude, arrangement is all-important. The grouping of each variety should be bold, and hard lines should be avoided. It is better to grow a limited number of different kinds of annuals in fairly large quantities than to fall a weak victim to attractive catalogues, and to buy innumerable single packets of all kinds of seeds. Sure and certain disappointment in the final result lies that way. Many considerations must govern the choice to plan for as long a flowering season as possible. In the nature of things, annuals are essentially summer flowers, and there can be but little colour in the annual border until the middle of June.

Annuals are divided for cultural reasons into two classes, namely, hardy and half-hardy. Hardy annuals are sown where they are to flower, either in the early autumn to flower the following summer, or in the early spring to flower the same year. The time of sowing depends, of course, both on the flower under consideration and the climate of any particular district. Half-hardy annuals are sown later in the open, or, better still, they are raised in cold frames or a cool house in the early spring, hardened off and transplanted into permanent places in May. This is a very sure method, although it involves extra labour and equipment.

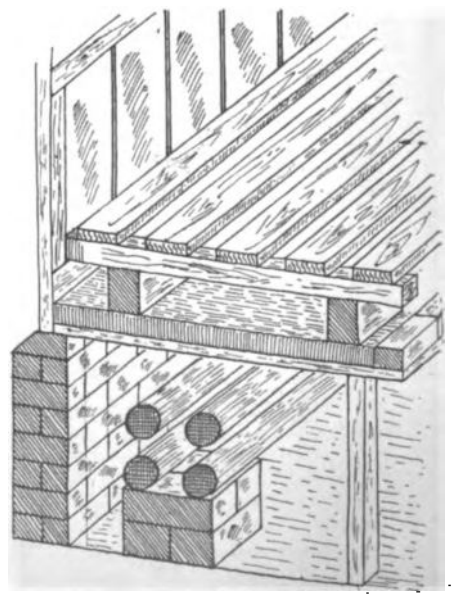
The culture of annuals is simple and straightforward. It may be summed up in a sentence by saying, sow thinly, thin drastically, hoe regularly, stake

SUCCESS WITH GLOXINIAS

IT is seasonable to talk of the gloxinia because now is the time to start the old corms into growth and also to sow seeds to produce flowering plants during the summer. Probably the gloxinia has to bear the opprobium of being an old-fashioned flower, but it is scarcely more old-fashioned than the rose. Whatever may be said about it, it has great intrinsic beauty and a refined appearance, and though many are not aware of it, it is very useful as a cut flower. I have kept it in a warm room for a fortnight without changing the water. Unfortunately, it is a flower which does not lend itself to being packed on account of the bell shape of the flower. Its freedom of flowering and the ease with which it can be propagated add to its value as a flower for the amateur. Although it is usually grown in considerable heat, it does in much milder heat if the flowers are not wanted so early. So much in praise of the gloxinia, now let us see how it is grown to produce success.

For an early supply of flowers the old corms should be started into growth late in December or early in January. If the corms were

STARTING THE CORMS INTO GROWTH.



A DOUBLE STAGING FOR GREENHOUSES.

Digitized by Google

properly dried off, they will still be quite plump, but if they are inclined to be flabby, it would be well after removing them from the pots to soak them in water for a few hours. A good way to start them instead of putting them at once into small pots is to place them closely together in a box of finely sifted moist leaf-soil in such a way that the tops are just visible. They may then be placed a few inches above the hot-water pipes or in a similar position until they produce leaves. A light syringing will hasten the development of top growth, at which time they should be placed in a position where they will get more light. Not until they have made several leaves and a fair amount of root should they be potted singly. When they are removed from the boxes for the purpose of potting it will be found that quite a lot of roots will have been produced in the loose leaf-soil. They are now ready for the first potting, which should be done with the smallest pots which will comfortably accommodate the plants. As the leaves begin to form on the plants, spraying should cease. A good soil for gloxinias may be made up of well matured loam, leaf-soil, peat sand, and a little wood-ashes or charcoal. The potting should not be too firm, especially as the plants have been in the loose leaf-soil, and the corms must not be covered or else there will be damping of the leaves and growths.

Although it is not advisable to spray gloxinias, they like a moist atmosphere. This may be arranged by forming a double staging. The ordinary staging of a solid character should be covered with ashes or shingle, and about 4ins. above this build up a trellis staging on which the plants will be staged. It is then quite easy to damp the lower staging with a water-pot or a syringe whenever necessary. This method may be employed right up to the flowering period.

Careful watering, the maintenance of a moist warm atmosphere and a light shading during bright sunshine are the most important cultural points. Some difficulty is experienced by amateurs in potting when the leaves become expansive, as they are easily broken or injured. This difficulty may be overcome in the following manner. The plant is carefully removed from the pot in which it is growing and is stood on the bench. The larger pot into which the potting is to take place is then crocked and partly filled with soil in the usual way. Instead of putting in the ball of soil containing the roots as is usual, the smaller pot is put in the larger one in such a way that the rim of the smaller pot is slightly above the rim of the larger pot. The soil is then put round this pot and is firmed in the usual manner of potting. When this is done, the smaller pot is twisted and withdrawn, and in the cavity thus formed the gloxinia plant is carefully dropped. A 6in. pot will accommodate most gloxinias, though I have grown good specimens in a 7in. pot with success.

Care should always be taken in watering the gloxinia to prevent the water getting into the base, where there is such an accumulation of leaf and flower stems. This point must also be remembered when potting, and care taken that the base is not unduly covered. All plants should be tested with the pot-rapper before they are watered. Liquid manure may be given when the flowering pots are filled with roots and before the flowering is far advanced.

In the final potting I always like to put some decayed cow manure, a little of Peruvian guano and a little charcoal. A light shading from bright sunshine is advisable throughout their career, and is especially necessary during the flowering period. At that time there is a great strain on the plants and they must be kept well supplied with water, and never allowed to flag. The flowers should be removed as they show a tendency to fade, and it may be necessary to stake some of them to prevent them from becoming overcrowded.

Gloxinias may also be grown from seeds sown early in the year. These require careful sowing on a fine surface of sandy soil in a pan, previously watered, and then lightly covered with very fine soil. When the seedlings have made two leaves, they should be pricked off into fine soil and carefully nursed through their infancy. Later they may be boxed up and eventually potted. They will produce flowers the first year, and a selection of the best forms should be made and these propagated by means of leaf cuttings.

To prolong the supply of flowers, and to keep the stock young and vigorous, I have adopted the following policy with regard to gloxinias. The best of the old corms are dried off with a view to starting them in December to provide an early supply. In February the young corms produced from leaf cuttings the previous summer are started, and during January seeds are sown with a view of getting some new forms or a more vigorous stock. It is mainly from these that the leaf cuttings are taken.

WILLIAM F. ROWLES.

THE HANDSOME BLOOMS OF A MODERN GLOXINIA.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2

NOTES OF THE WEEK

PRIMULA DENTICULATA.

AMONG the capitate primulas there are some fine and valuable hardy species. From my travels in north-western Yunnan I especially remember two species—P. denticulata and P. Littoniana—which look very different. Unfortunately, the last one, the flowering spikes of which look more like those of an orchis than of a primula, seems as yet never to have been successfully established, at least, nowhere in central Europe. It grows in rather wet meadows on the mountains at an elevation of more than 10,500ft., and it ought to be quite hardy with us. But here it lacks, apparently, the wet misty summers and the long heavy cover of snow during all the winter. This is a great pity, because I can hardly imagine a more striking sight than a meadow covered with thousands of its dense spikes with the blue-violet open

THE PURPLISH FLOWER HEADS OF PRIMULA DENTICULATA.

flowers and the dark bright red buds of the upper half of the inflorescence.

P. denticulata, on the contrary, is a great old favourite of our gardens. It came first to us from the Himalayas, where it is as common as P. acaulis in Europe. In western China, too, it covers large tracts of mountain pastures soon after the snow is gone in March and April, with its dense, ball-like, many-flowered umbels of violet or purplish flowers, as shown in our picture. There are several garden forms, among them one called P. cashmiriana, which seems to be a natural hybrid between P. denticulata and P. capitata. The first has glabrous leaves without the farinose covering beneath, which is a good feature of P. capitata. The leaves of P. cashmiriana are somewhat mealy beneath, but, so far as I know, the plants more resemble P. denticulata. A good form with rich crimson-purple flowers is called Ruby, but I am not sure whether this form really belongs to denticulata or to the hybrid. P. capitata is represented in western China by a species called P. pseudo-capitata, and also by P. sphærocephala. According to Balfour, both can be easily distinguished from the true capitata by the much smaller corolla limb and the more globular head of flowers.

I collected seeds of another species in the Lichiang valley which has been described by Balfour as P. stolonifera. Unfortunately, the seeds got lost, but I suppose that Forrest sent good seeds home several times. He collected it twenty years ago in moist boggy situations by sides of streams south of the city of Lichiang-fu, where I found it too in 1914.—CAMILLO SCHNEIDER.

VIRGINIA STOCK—A BIT OF COLOUR.

AS a rule, owners of rock gardens do not take into account the worth of annuals sufficiently, contenting themselves by growing plants of a more permanent character. The failure of some of the latter in my garden in June, led me to sow patches of crimson Virginia stock and the result has been very pleasing. As is known, it is an annual which grows very rapidly, and, it was no sooner up than it commenced to bloom quickly, so much so that during August I have had masses of bright crimson patches among sombre looking stones. Several friends have remarked on the "bright bit of colour"—an unusual tint at that time of the year in a rock garden, and, doubtless, have taken a mental note as to the use of a very simple old annual, seed of which merely requires to be scattered thinly where flowers are wanted. Probably the fact that some of the seedlings which came up among the "pockets" felt the benefit of coolness there, as they bravely stood the drought in July, and by the end of August were a mass of colour.—W. F.

PERENNIAL EDGINGS.

FROM time to time evidence appears in these pages in the shape of photographs of old English gardens, in which it is plain how highly perennial flowering plants are appreciated, and not the least important to be noticed are the edgings to the borders.

There is much to be said in support of edgings of hardy flowering plants that, once established, do not require very much attention, beyond now and again curtailing their growth in order to keep them within bounds. I am aware of the objections raised by some as to perennials being a harbour of many enemies of the gardener, but even allowing for this, I venture to say that it is worth the risk. In one's own garden one remembers edgings of pinks, which in their flowering season fill the atmosphere with delightful perfume, and even during autumn and winter give a neat finish to a path. In the glory of the springtime we remember how resplendent are other paths with aubrietias, mossy saxifrages, purple thyme, thrifts in rosy pink and white; and how, as the summer approaches, the foliage of Cerastium tomentosum becomes silvery white, until, at length, even whiter blossoms follow with a rich prodigality. And who can do other than admire the beauty that comes where dwarf campanulas are planted, those clustered bellflowers that bloom in profusion in May and June, but give a smattering of colour right on into autumn if only they are relieved of their spent blossoms—sorts like C. carpatica, white and blue, and C. pusilla?—CLAREMONT.

THE ORANGE FLEABANE.

ERIGERON AURANTIACUS, the orange fleabane, is one of the race which ought to receive more favour than it has done. As a border plant it is only suitable for the front of the border or for edging beds of other flowers, but it forms a most attractive little subject for the rock garden or small rockery. It is dwarf in stature, being only about 6ins. high, and it bears in summer good-sized flowers of a true orange hue. It is understood to be one of the parents of that excellent "biscuit-coloured" hybrid E. Asa Gray. Probably it will have a still larger share yet in the production of other hybrid erigerons of orange and allied shades of yellow. But in itself E. aurantiacus is a capital little flower, of good, neat habit and eminently suited for the positions named above. It is quite hardy, and the only trouble the writer ever had with it was caused by the depredations of slugs, which in late autumn seem fond of cropping the plant down to the ground, and in spring these pests essayed to destroy the early growths. But this trouble is not one which afflicts E. aurantiacus alone. They also attack such plants as Aster alpinus. As has already been said, it is hardy, but should have a well drained loamy soil, lightened by leaf-mould or peat and, in addition, some sand if still stiff. It evidently likes a sunny place.—S. ARNOTT.

SWEET BAY AS A DECORATIVE SHRUB.

WHY is it that the sweet bay bush is so seldom found or planted in flower gardens or pleasure grounds? For such purpose it appears to be quite overlooked by gardeners and planters. Here we have it among shrubs near to the house, from which position passers-by can gather a leaf for the peculiar fragrance for which the bay tree is noted or stay and peruse the general effect of its habit and dark green foliage against other like subjects. While the common laurel, the green euonymus and box can be used with advantage in many places, I would aver they are often placed among good class shrubs which sites would be richer and more elegant were they planted with a specimen or trio of specimens of our subject, Laurus nobilis. Sweet bay plants ought not always to be dubbed down in the kitchen garden—the spot where they are found, if found at all—but should be given a chance among the better shrubs of the flower garden proper. Presumably the relegation of the bay to the culinary department is on account of

Digitized by Google

SAXIFRAGA STRACHEYI WITH FLESH-TINTED BLOOMS.

its being occasionally sought after for seasoning uses.

The hardiness of the Poet's Laurel is sometimes tested in severe winters where the soil is cold, but if not killed outright the root-stock shoots up again. To avoid such cutting back, let its planting be in such a position that some protection will be afforded by growing shrubs, and see that the soil is free working and drained. Or, in extreme cases, a sheltered corner or wall could be allowed for its development. Sweet bay is not difficult to propagate either from cuttings put in a cold frame, or from growths bent down and layered.—C. T., *Ampthill Park.*

A FINE MONKS'-HOOD.

ACONITUM WILSONI is undoubtedly one of the finest of monks'-hoods, and worthy of a place in every herbaceous border. It was introduced some years ago from Western China by Mr. E. H. Wilson when collecting for Messrs. J. Veitch and Sons, Chelsea. A species of great garden value, it attains a height of 5ft. to 7ft.; but under favourable circumstances it will grow even 8ft. or 10ft. high. The colour of the flowers is a deep violet blue, and these commence to open in September on the central spikes, the display being continued throughout October by the lateral spikes that appear on the stem.

Not only is it useful for the borders, but it is a splendid subject for large isolated beds near the lawns, and in such a position I saw it at Kew ten years or so ago. Strong clumps can be divided during the winter months, but an easy method of propagation is by seeds. A. Wilsoni produces these in quantity, and a few should be sown directly they are ripe, the remainder waiting till spring. They can be raised either in a cold frame or outside. When the seedlings are large enough, they are transferred to nursery beds, in lines 1ft. apart, and here they can remain until they reach flowering size.—T. W. B.

NOTES FROM A NORTH-EAST YORKSHIRE GARDEN IN 1925.

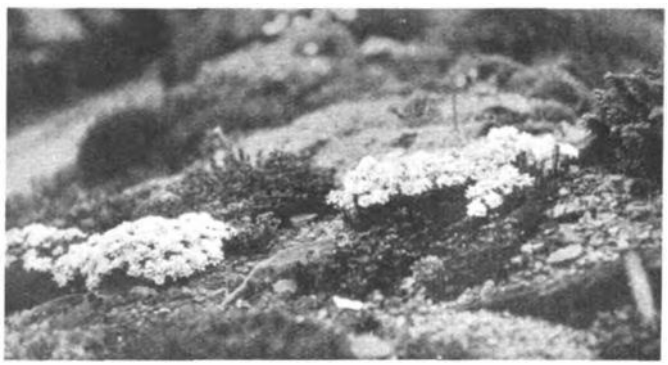
TOWARDS the end of April Primula denticulata alba was particularly beautiful in several parts of the garden. Some of the plants have been in their present positions for many years. They always flower well and it is much the most effective of the group in my experience. It has lighter green foliage than the types or P. cashmiriana form and does much better with me than the latter, which has a tendency to rot off in damp winters along with intermittent frosts.

At the same period Saxifraga (Megasea) Strachey. flowered exceedingly well with its uncommon flesh-tinted flower spikes, which open out before the leaves are developed, it is quite the prettiest of the megaseas that I have had experience of. The flowers are liable to be damaged if exposed to frost and early morning sun.

Sanguinaria canadensis, the Canadian Bloodroot (so called from its roots "bleeding" when damaged), flowered freely in a fairly dry position near Phygelius capensis, the foliage of which sheltered the position in the summertime. It has occupied this position for some years, the pretty frail paper-white blossoms being pushed out from the closely folded, undeveloped leaf, which seems to act as a protection at its inception. The bluish green lobed and scalloped leaves, when fully developed, are extremely decorative.

On my "island" moraine Petrocallis pyrenaica has grown into quite a good plant in the ten years it has occupied its present position. It was completely covered with its dainty pale pink petalled flowers squat on the green cushion at the end of April.

In May the Spanish thrift, Armeria cæspitosa, with Iberis petræa (saxatilis), provided a pleasing association, the contrast between the rosy pink flowers of the armeria and the snow white flowers of the iberis being particularly fine. Iberis petræa is quite the best of the family and a plant that Reginald Farrer thought highly of; the true plant is rarely seen in gardens visited. It is a very slow grower (possibly slower than usual in moraine), and the plant shown has taken ten years to attain its present size.



A WELL-FLOWERED CLUMP OF IBERIS PETRÆA.

Towards the end of June the finest and latest flowered of the encrusted saxifrages, S. cochlearis, produced its dainty spikes of white flowers freely in a vertical stone crevice fully exposed to the sun. The past summer has been rather a disastrous one for my saxifrages. The eight or ten weeks that we had in the north of England, from mid-May to July, with practically no rain (.08 in June) and considerable periods of hot sun, burnt off my saxifrages wholesale. Many of the plants had occupied these positions for ten and twelve years and grown into a considerable size, including a patch of S. oppositifolia about a yard across; large plants of some of the Aizoons and most of the Kabschias, such as S. Burseriana, S. apiculata, S. sancta, S. Haageii, S. Salomoni, S. Irvingii, in fact nearly all the smaller species, suffered mostly past recovery.—T. ASHTON LOFTHOUSE, *Linthorpe, Middlesbrough.*

THE LAUREL AS A WINDBREAK.

THERE are few plants which can be relied upon to produce in a comparatively short time so efficient a shelter or windbreak as the laurel. True, hedges formed of laurel are not so neat and trim in appearance as those composed of close-growing and shorter-branched subjects, but at the same time a very satisfactory evergreen hedge can be obtained by keeping it well cut back. Systematic pruning at the appropriate time is very necessary if it is desired to keep a laurel hedge within narrow limits.

In the case of laurels planted purely as screens or as windbreaks, however, and not as a formal hedge, there is, as a rule, no necessity to keep the plants cut back so drastically.

Rotundifolia is the best variety to plant. It is stronger growing than other varieties, hardier and flourishes in shady positions.

It is surprising how tall laurels will grow when in a congenial soil and situation. When in the neighbourhood of Southampton recently a very fine specimen was pointed out to me. It was a magnificent example rising up as flat as a wall some 25ft. It had been carefully tended and pruned, and the unbroken surface of its front conveyed an imposing impression.—HOWARD H. CRANE.

THE TREE MALLOW.

A VERY distinctive plant which is neglected by many gardeners is the tree mallow (Lavatera arborea). Many people, when on holiday, must have noticed the tree mallow growing quite close to the sea, where, in the winter, it must be deluged with salt spray. The common idea seems to be that the species will not grow in inland places, but this is incorrect. The tree mallow will flourish anywhere, save, perhaps, in the bleakest parts of the kingdom. The species has the appearance of a small tree and, in favourable circumstances, will grow to the height of 10ft. The woody stem branches into a broad, compact and very leafy head. The leaves are softly pubescent all over and forms with variegated foliage are common. The pale purple flowers are of good size, and at times are produced in great abundance; but, even if they were not, the tree mallow is always attractive. Best results are secured with this plant on rather dry sandy soils, although it has proved to be a success almost anywhere if the drainage of the land is in order. The tree mallow is a biennial, and it is necessary to raise seed annually. As a matter of fact, the tree mallow usually sows itself freely.—S. LEONARD BASTIN.

THE TREE MALLOW, A HARDY BIENNIAL.

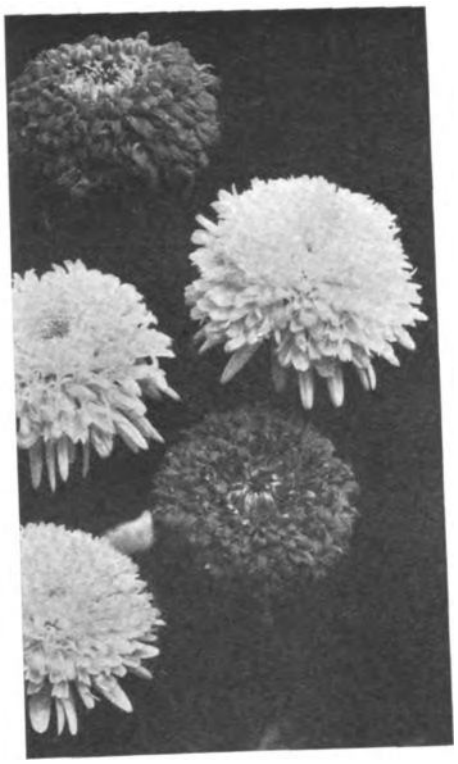
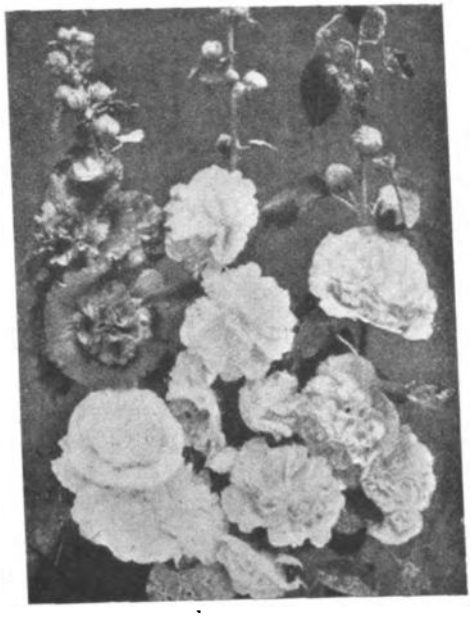
USEFUL FLOWERS FOR



DOUBLE PYRETHRUMS.



IN these dead days when the gardener's imagination has to be quickened with the seed order in front of him, we give these two pages of flower pictures as a hint that old favourites of past years must not be forgotten. For colour and general utility and ease of growth they can hardly be surpassed; in fact they are a necessity when the aim of the gardener is the charm of the old fashioned garden.

A FINE RACE OF ANNUAL POPPIES.

FEW PLANTS HAVE THE CHARM AND GRACE OF THE NIGELLA WITH ITS OLD-FASHIONED NAME OF LOVE-IN-THE-MIST. THEY ARE STILL CONSIDERED AS ONE OF THE BEST OF THE BLUE ANNUALS.

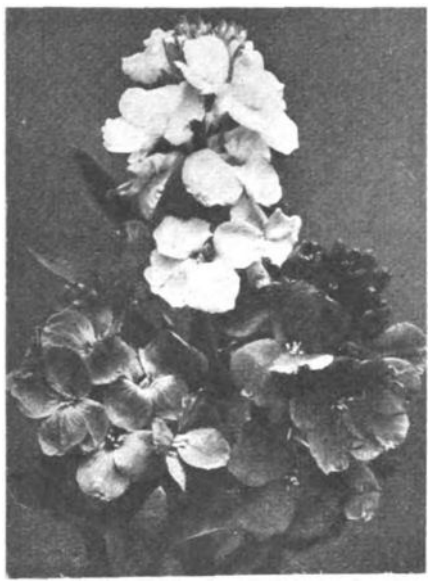
EDS AND BORDERS

NEW varieties may come and go, but the background for many of our most successful gardens is still made up of the hollyhock, the aster, the wallflower, the antirrhinum and many another old and tried friend. It is as well to remember that flowers such as these not only look well in beds and borders but act as fillers for gaps in the garden scheme that might otherwise remain unsightly.



THE DWARF ASTER IS ONE OF THE TRIUMPHS OF THE RAISERS OF NEW VARIETIES OF ANNUALS, FOR FEW FLOWERS GIVE SUCH A DISPLAY IN SUCH A SMALL SPACE.

THE VEGETABLE SEED LIST

easeless activities and changes age, horticulture has its share, the products of the kitchen -day are much more plentiful than was the case in previous s. Varieties are more numerous, higher, and the demands of for both early and late supplies ant. Hence the annual pre- of the seed list becomes some- an art, an art which is a to the newly appointed gar- his first place, but one which joy to the old custodian, in minds him of past successes with this or that variety. re still many people who fail that flavour in vegetables does do not give this point special yet they would probably be

SUTTON'S EARLY GIANT PEA.

o proclaim that a variety of ld be judged on flavour. ar, then, that to ensure success should only consult the lists houses of reputation. The ed are in no case excessive, pparent extra cost can usually y sowing to meet requirements adopting the not unusual sowing for excessive thinning ing away. It is much safer ise in quantity than in quality. one cannot, in an article scription, choose the varieties grower and every purpose, y be helpful to many readers t varieties of vegetables and t are reliable and useful for ge kitchen garden.

sparagus is grown to lift crowns , it is usual to sow a few rows r and grow for three years. purpose, Connover's Colossal ing Giant are excellent.

Once globe artichokes of a good type are obtained, it is better to propagate by division, as seedlings vary in type. a packet of seed of a good selected strain will usually give some of sufficiently good type to propagate further.

BEANS.

The modern Green Windsor and Giant Longpod Broad Bean far surpass the old Windsor types and Johnson's Wonderful of fifty years ago; but it is interesting to note that Beck's Dwarf Green Gem, also included in lists of that period, is still a much grown early variety and is often considered a table delicacy owing to its small seed.

Among dwarf French beans, Superlative and Magpie are excellent for forcing and also for early work outside; while for main crop it is difficult to beat a good selected strain of Canadian Wonder. Best of All runner bean is a variety of outstanding merit, the flesh being of superb quality in spite of its large size; and the usefulness of Tender and True as a climbing French is indisputable.

Beetroots are in demand all the year round, and for early work a good globe variety is essential. For main crop a selected strain of Dell's Crimson is excellent, as is also Cheltenham Greentop, the flesh of which is of an intense red colour. Sea-kale Beet is useful for late summer and autumn supplies.

Brussels sprouts are among the most important of winter vegetables. The tendency of some modern varieties is to produce buttons of too large a size, and those who prefer small sprouts will find that Dwarf Gem is an excellent variety for early supplies, while Aigburth and Wroxton are still among the best as main-crops.

CAULIFLOWERS.

A supply of cauliflowers can be maintained during the whole year by a wise choice and good management of varieties of broccoli and cauliflower. For the winter season, supplies may be relied on in rotation from the following varieties: Michaelmas White, Autumn Protecting, Winter Mammoth, Christmas White, Snow White, Knight's Protecting, Leamington, Eastertide, Late Queen, and Whitsuntide. A packet of Purple Sprouting should be sown, as it is most useful in very severe winters. For summer supplies of cauliflowers I know no finer variety than Early Erfurt, and by successional sowings continuous supplies may be maintained throughout the summer. For late work Walcheren and Autumn Giant are excellent.

Spring cabbages do not always behave alike under cultivation, and the shrewd grower will not pin his faith to one variety, but grow two or three. For August sowing, Harbinger, Ellam's Early, Offenham and Flower of Spring are excellent varieties; for spring sowing, Wheeler's Imperial, Improved Winnigstadt and Enfield Market are good; while for winter supplies Christmas Drumhead and Rosette Colewort cannot be beaten.

For Savoy cabbage, to be cut from September to January, Dwarf Green Curled, Drumhead and New Year should be grown. Couve Tronchuda, or Portugal Cabbage, makes a delicious summer vegetable and is easily grown.

The demand for carrots is incessant, and young roots grown in frames or on early borders are always appreciated. For this purpose, Inimitable Forcing, Champion Scarlet Horn, and Early Gem are ideal varieties; while for the main crop Scarlet Intermediate cannot be beaten.

Celery provides a choice winter vegetable and salad, and, although the giant strains may have attractions from the exhibition point of view, I am quite content with good strains of Standard Bearer and Solid White.

Kales or borecoles are very useful where large supplies of greens are in demand in winter, and are a great standby in long periods of inclement weather. Curled Scotch, Hardy Sprouting and Thousand-headed are varieties well worth growing.

Leeks are in demand during the greater part of the year, and successional sowings should be made of Improved Musselburgh and The Lyon from January till April.

ONIONS.

Onions are in constant demand throughout the year, and present some difficulties to the grower on light soils. When spring sowings fail, autumn sowing should be resorted to, using the same varieties as one would in the spring, as well as those of the Rocca and Tripoli type. A selected strain of Ailsa Craig is impossible to beat and should always be grown. James Keeping, Bedfordshire Champion and Brown Spanish are also excellent varieties.

Digitized by Google

There has been less change in the variety of parsnips during the last fifty years than in any other vegetable, but probably the old types have been much improved by selection. It is interesting to note that The Student was evolved by continual selection from the wild type by Professor Buckman and still remains a standard variety of to-day.

PEAS.

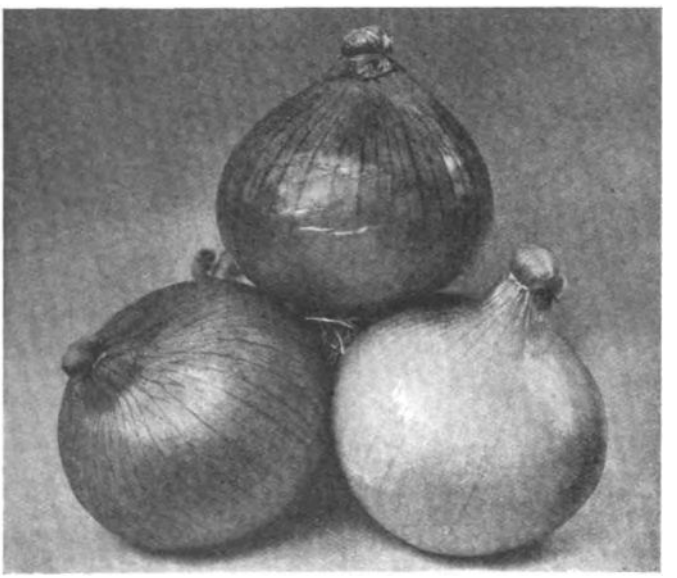
No vegetable ranks so high in importance during the summer months as peas, and modern varieties enable the grower to maintain supplies from May till October without the aid of glass. For autumn sowing, there is no variety to beat Pilot. For spring and summer sowing the following varieties may be sown in succession at intervals of ten or fourteen days throughout the season and in rotation as written: Eight-Weeks, Pioneer, Reading Gem, The Sherwood (a remarkably sweet pea), Early Giant, World's Record, Up-to-date, Selected Duke of Albany, Centenary, Peerless, Quite Content, Perpetual, Matchless, Autocrat and Selected Gladstone.

Scorzonera and salsafy are both useful root vegetables and should be grown to augment variety in the winter season.

Spinach is in great demand as a light dish during the hot summer months, and it is just at this time when it is most difficult to obtain. Previous good cultivation of the soil is an essential factor, and the variety Victoria is less prone to run to seed than some others. For late summer and early spring supplies Longstanding Prickly is preferable, as it is somewhat hardier. On very light soils, where summer production of succulent leaves becomes very difficult, New Zealand Spinach is a good substitute; while where winter supplies are needed Perpetual Spinach should be grown.

Succulent roots of turnips are always appreciated, but not always easy to produce in first-rate quality. Early Snowball and Early Milan are excellent varieties for early work, with Six-weeks for successional sowing.

Tomatoes should always be tried, for excellent crops can be obtained from outdoor plants if advantage is taken of positions of shelter which obtain in every garden. Open-air and Sunrise are good varieties.



THE FAMOUS AILSA CRAIG.

Marrows provide an excellent summer vegetable, but, except for special purposes, large fruits are not desirable. A good strain of Custard gives abundance of small fruits of delicious flavour. Tender and True, Pen-y-byd, and Moore's Cream are also excellent varieties.

SALADS.

Lettuce is the most important salad grown and can be produced from April to November, or December even, without the aid of glass. The cabbage varieties are quicker in maturing and, for spring and summer growing, Ideal, Heartwell and Satisfaction should be grown, with All the Year Round and Hammersmith Hardy Green to stand the winter. Of cos varieties, Superb White and Little Gem are good for summer use, with Hicks' Hardy White for autumn sowing.

For winter salads, Batavian Endive and Witloof Chicory are the finest grown and are of the easiest possible cultivation, though blanching is, of course, necessary. Corn salad may be grown outside for autumn and winter supplies, and is excellent for mixing with endive or chicory; while a few roots of dandelion may also be grown to add to the variety.

Where frames are available, French Breakfast Radish may be grown, but is not much in request until the spring; and with a heated house, regular supplies of mustard and cress throughout the winter are easy of attainment.

No vegetable list can be complete without a reference to herbs, and, besides the usual parsley, thyme and sage, a packet of balm, basil, borage, chervil, fennel, horehound, hyssop, marjoram, purslane, rampion, savory and sorrel should be included. W. AUTON.

SWEET PEAS

IMPRESSIONS OF THE 1925-26 NOVELTIES.

THE growing of novelties—whether they be flowers, fruits or vegetables—the first season of their introduction undoubtedly exercises a great fascination, not only among amateur, but also among professional gardeners. This is more particularly true of those horticultural enthusiasts who have a decided preference for one particular type of flower or vegetable. In the popular flowers—roses, carnations, sweet peas, gladioli, etc.—many new varieties are placed on the market each season, and unless one endeavours to keep in touch with the improvements, it is an easy matter to get quite out of date.

In sweet peas alone over a score and a half new varieties are being offered by the various raisers for the first time this season. Past experience warns us that probably not more than half a dozen of them will ever become really popular or displace the present-day favourites in their respective colour sections. On the other hand, we know from experience that very rarely can it be truthfully said of a sweet pea novelty that it was not worth its garden room, and if one is fairly familiar with the best of the varieties which have been introduced in previous years, there is very little risk of disappointment if a careful choice of the newcomers is made.

Very few will disagree with the statement that sweet pea novelties are inexpensive. When one realises the years of patient hybridisation and selection which have, in most instances, preceded the marketing of a new sweet pea and the comparative prices of new dahlias, roses, gladioli or carnations, we sweet pea growers should not complain if we are asked to pay one penny or, perhaps, three halfpence a seed. I firmly believe that the flower owes much of its present popularity to the fact that its novelties can be purchased so reasonably; the very best in existence are within easy reach of the modest purse.

In the following notes I will try to convey the main characteristics of most of the 1925-26 novelties, the majority of which I have either seen growing or exhibited. By the way, I do not allow first impressions formed at shows to carry me away, for the blooms exhibited—as a general rule—have been grown on the cordon or "single-stem" principle, perhaps shaded, and often come from under glass. Sometimes, points which when growing them naturally in one's own garden would be considered faults—such as lack of vigour, liability to fade in bright sunshine, etc.—are not in evidence among such blooms.

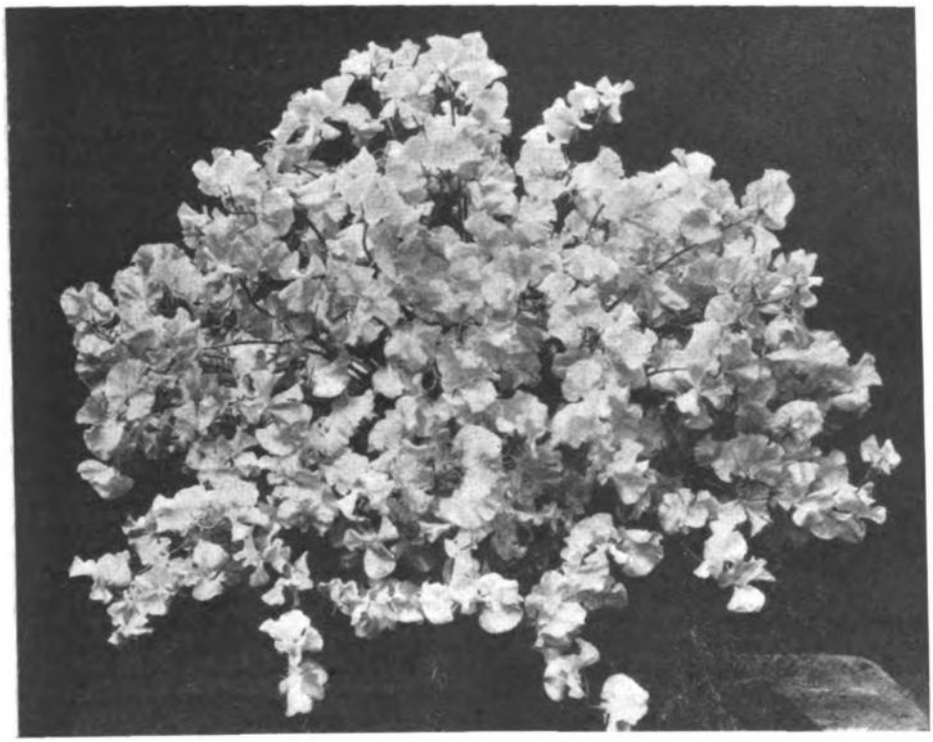
I think writers in describing varieties of sweet peas, generally speaking, attach too great an importance to their exhibitive value as distinct from their value to the ordinary grower who grows his or her sweet peas naturally and not

Digitized by Google

intensively. While I recognise the great influence exhibitors exert on the popularity of a pea, they are, after all, very much in the minority, and in my comments I intend to approach each one from the point of view of the average grower.

BLACK BESS (Bolton and Son).—Is a new shade in sweet peas difficult to describe, about midway between the colours of the deep blue Commander Godsal and the black-maroon The Sultan. It is really a bronzy dark blue with the metallic lustre which characterises many of Messrs. Boltons' past novelties in the dark blue or blue-mauve shades. Black Bess is perhaps more pleasing than its description conveys, and but this may not necessarily mean that it is not so vigorous as the latter, for some very vigorous growers are short jointed.

CORAL GLOW (F. C. Woodcock).—I saw this novelty growing both last year and this, and its glowing, deep coral shade pleased me. It is very bright, and equally effective both in daylight and in artificial light. For garden and home decoration it will be hard to beat. There is no trace of harshness in its tone. I advise exhibitors to confine it to one stem only and to give it liberal cultivation, for it has a tendency to produce too many "threes" if poorly treated.



GOLD CREST, A 1926 NOVELTY REMINISCENT OF PRESIDENT HARDING BUT OF A LIGHTER AND MORE GOLDEN SHADE.

I liked it both at the N.S.P.S. trials and as exhibited. It will appeal to all who admire the dark shades.

BRITANNIA (E. W. King and Co., Limited).—Imagine Advance on a cream ground and you have a fairly accurate mind-picture of the delicate and pretty colouring of this pea. It is a deep cream, softly flushed rose, which makes a very attractive bunch. I feel sure it will be generally admired. Another 1926 novelty, Queen of Roumania, is somewhat similar, but deeper toned.

CENTAUR (J. Stevenson).—There are four newcomers in the cerise colour section this year—Centaur, Coral Glow, Peggy and Ryburgh Cerise—but all four will most certainly have to be of unusual merit to displace the present deep cerise favourites Coralline and Charming, both raised by Mr. Stevenson. Centaur is claimed to be richer in colour than either Charming or Coralline, and this alone is sufficient to make one pause before passing it over. The catalogue description states that Centaur is not quite such a tall grower as Charming,

CRUSADER (Thomas Cullen and Sons).—My notes describe this novelty as a richer George Shawyer, and no further comment of mine is necessary other than I should not be surprised if Crusader superseded that popular older variety. Apparently it has no faults respecting size of bloom or vigour, but I cannot at present say whether it is more sunproof than others of its class. The raisers' description is "Standard rich orange-salmon, wings salmon with slight rose shading, almost a self coloured flower."

DAINTY MAID (Thomas Cullen and Sons).—This novelty has favourably impressed me. Its colour is a soft, but rich, blush pink on a white ground, and its raisers claim it to be the finest and largest blush pink in existence. I hope it may prove to be, for Valentine has had a long innings and we need a better blush. From what I have seen of Dainty Maid I should say its colouring is nearer to Felicity than to Valentine, being slightly deeper than the former. As growing at the N.S.P.S. trials its shade seemed to me to vary very slightly on individual plants, but I see the F.C. have marked it "True," and in any case it is not a serious fault, for some of the very best of recent pinks and cream-pinks have that tendency.

DELICE (A. Ireland and Hitchcock).—This is described as being an exhibitor's variety, giving very large flowers and plenty of stem without being inclined to coarseness in any way. It is pure pink.

GOLD CREST (R. Bolton and Son).—The colour of Gold Crest as exhibited was pleasing, rather reminiscent of The President Harding, but several shades lighter and having more of a golden hue. Evidently it needs some measure of protection from the sun to preserve its beauty, but we have the assurance of its raisers that "Gold Crest is as nearly sunproof as we have yet secured." As shown it did not appear to lack vigour or size, but I would strongly advise exhibitors to confine it to a single stem and to give it liberal culture to be on the safe side.

IVORY PICTURE (R. Bolton and Son).—With the exception of Madam Sarah Grand, a 1925 novelty, no ivory variety had been introduced for years. I have seen Ivory Picture growing and exhibited, and consider it a much better pea than Madam Sarah Grand. In size, shape and vigour it closely resembles Picture, and I feel confident it will give general satisfaction. Of course, it has not the depth of colour of the cream varieties, but is, nevertheless, delicate and pleasing. It is dark seeded. C. H. A. S.

(*To be continued.*)

CORRESPONDENCE

THE TALLER-GROWING CAMPANULAS.

SIR,—Referring to the note on campanulas in THE GARDEN, on page 716, December 19th 1925, which "T. W. B." has so admirably written, I would like to add my testimony to the extreme value of C. lactiflora in the back portion of the herbaceous border. I think the reason it is not more grown, is that, although its normal height is up to 5ft., it does not attain to this for several years, it does not like transplanting except as small plants, when the first year after planting it rarely attains more than 2ft. or so, so that if planted as the background it is liable to be smothered by strong-growing neighbours.

Given soil of sufficiently moist character and left undisturbed it is a noble plant, having widely branching heads in dense panicles, literally hundreds of flowers out at one time, and lasting for quite a long period. Flowering earlier than phloxes, etc., it fills an important position in the border scheme if left untransplanted for five or six years, and merely mulched with manure.

"T. W. B." rightly, in my opinion, classes the persicifolia section as being the most popular, of which Telham Beauty is one of the best. Probably, however, he is not yet acquainted with the varieties of the recently introduced section, the three following of which have also been honoured by the R.H.S. award of merit: Crescent, pure white; The King, deepest blue; Shirley, china blue. These are all of the coronata or cup and saucer types, of robust habit. Everest, soft blue; Snow Queen, pure

Digitized by Google

white; Queen of June, mauve blue. These attain to the height of 4ft. to 5ft., producing sturdy graceful spikes of single bells.

I think the French variety, Fleur de Neige, far superior to Moerheimi, the intense purity of its double white flowers quite eclipses the older form. Unlike C. lactiflora, the persicifolia types I find respond to annual division, and the spikes are always individually finer when so treated.—E. A. LADHAMS, *Southampton.*

VOLES AND FIELD MICE.

SIR,—Mr. A. T. Johnson should be able to get rid of the field mice and voles by constant use of Little Nipper mouse traps. The best baits for these are nuts, either brazil, Barcelona or what are commonly known as monkey nuts. The traps should be set in lengths of drain pipe, just large enough to allow the trap to spring, say 4ins. diameter. This makes the trapping quite independent of the weather and there is much less risk of small birds being caught. Cats and other animals will run away with a trap in which a mouse is caught; they cannot do this when the trap is set as advised above. If Mr. Johnson could sink a stone trough with smooth sides level with the ground and with a few inches of water in it, he should be able to catch the mice wholesale by smearing small lumps of lard on the sides of the trough, just so far down that the mice cannot reach them without overbalancing.—C. F. ORMEROD, *Stroud.*

SIR,—Every reader of THE GARDEN who loves a flower, plant or tree will sympathise fully with "A. T. J.," page 733, issue, December 26th, 1925. The destruction as described, must be more than upsetting to the mind of a serious cultivator. "A. T. J." does not say, in detail, how the jars were prepared, as referred to in the prominent daily paper. If such articles are sunk into the soil and merely filled, or partly filled, with clear water, voles are going to be wise and make off in another direction. But I can assure "A. T. J." that glass jars, with shoulder tops, three parts filled with water and buried level with the soil will be the means of trapping voles in large numbers if some mutton fat is smeared inside, just under the shoulder-like neck of the jar. Voles and also house mice love mutton fat and being unable to resist it, reach down, overbalance and fall into the water. The jars should be about 7ins. deep. As many as nine have been so caught in one jar. These traps are not difficult to place, they are harmless to all domestic animals and do not require attention very often except in the matter of taking out drowned voles; this, I hope, will be the case with "A. T. J." if he thinks fit to make an experiment in the way described.—G. GARNER, *Southampton.*

LACHENALIAS AT CHRISTMAS.

SIR,—In your description of Lachenalia Boundii (THE GARDEN, December 26th, 1925, page 733), it is said "it represents a new break in Lachenalias by flowering at Christmastime." May I say that when I had L. pendula in considerable quantity I could always count on it flowering at Christmas and have sent notes to various papers advocating its being grown for a bit of red at that season. L. rubida I only had for three or four years and then lost it. It think it used to flower in November, so there is nothing very wonderful in L. Boundii being in flower on December 15th.

L. PENDULA FLOWERING BEFORE CHRISTMAS.

I enclose a photograph of L. pendula taken in Guernsey on December 14th. It was raised by Mr. William Mauger from seed sown in June, 1922, and the bulbs were potted on July 18th. It is interesting to compare the two pictures. I send this note to say if Boundii is not yet in commerce, pendula is and with proper cultivation it can be had in full flower before Christmas. The photograph speaks for itself.—J. JACOB.

ANNUALS OF GOOD REPORT.

SIR,—Your correspondent, "W. F.," in the issue of THE GARDEN for December 26th, 1925, asks for opinions as to the twelve best annuals for all round usefulness. Here is the list of what I usually grow. I may add that they are wanted chiefly for cutting. Sweet peas (twelve varieties); Aster sinensis, mauve; Cosmos (mixed); Lavatera rosea and alba splendens; Sunflower Munstead Primrose; Sunflower Sutton's Red; Calendula officinalis, Sutton's Orange King; Nigella Miss Jekyll; coreopsis (mixed); eschscholtzia (mixed); Alyssum maritinum Little Dorrit (for edging); Ionopsidium acaule (for cracks in paved paths).—R. E. H., *Bath.*

TENDER SHRUBS IN THE FROST.

SIR,—It may be interesting to those who grow sub-tropical and other tender shrubs in favoured localities to know the effect of the first hard frost we have had in Jersey for eight years. On the night of December 1st the thermometer on the ground registered three degrees of frost, on the two succeeding nights four, and on Friday the 4th seven, after which, to the moment of writing, the frost passed away. Everything stood the cold well till the last, severe night, then the following wilted. Psoralea glandulosa, Tagetes lacera, Datura suaveolens, Myoporum crystallinum, Habrothamnus aurantiaca, Cestrum Parqui and Solanum aviculare (these were young plants and had been weakened by an attack of potato disease).

Added to these, was Fuchsia arborescens. This is a shrub well worth growing; I have never seen it elsewhere in England or the Channel Islands. Up to last Friday it was covered with its rosy-purple panicles, and, indeed, it has been in almost continual flower since July. Now flowers and leaves are a sorry sight, though it is not otherwise injured. Oranges and citrons are untouched; we grow all the citruses under the shelter of a wall. Guava cattleyana, also under a wall, only slightly frost bitten; olives, eucalyptus and oleanders unharmed. But a week or a fortnight of over seven degrees would be serious for the more tender things.

The following trees and shrubs are in flower. Acacias Whanii, uncinella, brachybotrya, Carteri, obliqua, retinoides, Sibertiana, and most of the other species in bud. Sollya heterophylla, Cytissus fragrans, Pieris japonica (just breaking), Solanum crispum and jasminoides, Cassia corymbosa, Desfontainea spinosa, Westringia rosmariniformis, Sempervirum arboreum, Colletia horrida, Berberis Bealii, Veronica macrocarpa, Manettia bicolor. All the hydrangeas, except paniculata and quercifolia are still in full bloom, and I brought large blue heads into the house from the garden the day after the frost.—ATHELSTAN RILEY, *Manoir de la Trinité, Jersey.*

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS

EXHIBITION SWEET PEAS FOR AMATEURS.

AMONG the readers of THE GARDEN, there are probably quite a few who are particularly inclined to the growing of exhibition sweet peas. If the following advice is carefully carried out, one should be able to produce flowers that would vie for first place with the best at local or county shows.

There is no necessity to grow more than forty plants, as these will yield sufficient for an ordinary private exhibit.

In the middle of January sow the seed, one in a "sixty" pot, and allow for about 15 per cent. non-germination. The seed pots should then be placed in a slightly heated greenhouse until germination takes place. When the plants are about ½in. high, transfer them to a cold frame. Lights should be placed on at night, if cold, for the first few weeks. Gradually harden the plants off, until by the beginning of April, splendid little plants of a very sturdy nature will have been obtained. They can then be planted out alternately in well prepared ground, preferably a trench.

If the weather is very hard, protect the young plants with sprays of gorse or fir. In a week or so, the stakes can be put up. Long, straight bean poles are the best. Allow one to each plant, and lash them together at the top. As the plants grow, tie each one to its stake. Pinch out all side shoots, and cut off *all* tendrils.

At the beginning of May mulch the plants with light pig or cow manure. This will be extremely beneficial should a hot summer be forthcoming. Very soon flower buds will appear, mainly twos and threes. Keep all these vigorously nipped out, until the fives, sixes and sevens appear. Then remember, the more the flowers are cut, the more flowers the plants will throw. If the flowers are wanted for a particular show, keep all the buds picked off until fifteen days before the show.

Should the season be hot and dry, water *thoroughly* a few times. To give a little every day is useless. The flowers are best picked overnight and stored in a cool, dark place, such as a cellar.

Digitized by Google

With regard to varieties, it is impossible to say which are the best, but the following are all first-class ones. Mascott's Scarlet (scarlet), Constance Hinton (white), Mrs. Tom Jones (blue), Warrior (maroon), and Picture (cream pink).

As to the arrangement of the exhibit, each one has his own particular taste. Asparagus foliage makes a delightful combination with sweet peas, but it is as well to find out beforehand whether or no foliage is allowed; for when at Wisley, I showed sweet peas with asparagus, at a local show, and got disqualified on account of it!—J. BIRKENTALL.

HOLLYHOCKS.

QUICK of growth, stately and beautiful when roped with blossoms, hollyhocks are among the most attractive plants one may have in a garden, given a suitable position. Unfortunately, it has to be said concerning them, that their culture is not always understood, and, not infrequently it happens that instead of carrying one or two stems bearing well developed flowers, one notices colonies of indifferent, weak and rust-ridden stems with blossoms not to be compared to plants upon which care and culture have been bestowed. Not only are these noble plants prone to throw up suckers, which, if left, smother each other, but what is equally bad, the soil becomes worn out, and so rust disease is encouraged. My experience prompts me to say that the best way to avoid the pest referred to is, either to propagate offshoots or to sow seed and treat as biennials. The term "gross feeder" is applied to certain plants that take nutriment out of the ground very quickly, and hollyhocks certainly come within this category. The soil therefore needs to be enriched periodically. Where rust disease has once asserted itself, the wisest course to pursue is to dig up and burn the plants, treating the soil with lime afterwards, and avoid planting hollyhocks there for a season or two. In the majority of instances of affected plants which have come under my notice, the source can be traced to colonisation over a number of years, and to the soil having become greatly impoverished in consequence. Hollyhocks are worth culture which entails trouble, and freedom from disease is only achieved when this is appreciated.—W. F.

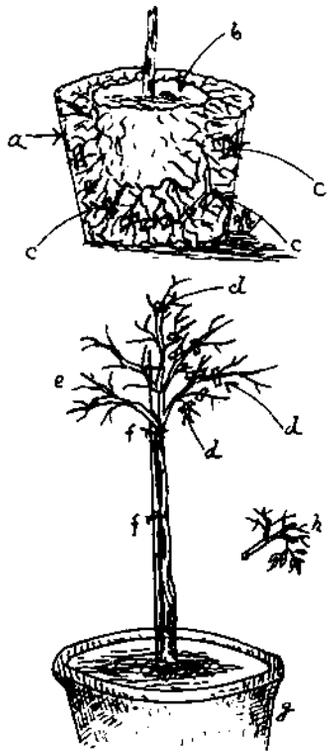
GREENHOUSE GERANIUMS.

MANY and varied are the plants now cultivated to furnish the greenhouse; but among all the grandeur of the new and varied forms of flowering plants, geraniums still hold a prominent place. They are general favourites with cottagers, amateurs and gardeners alike. Although in winter the plants are in a semi-resting state, they keep on flowering, and one is able to cut a bunch of prettily coloured blooms throughout the darkest days of December.

Not only do geraniums provide rich red and striking colours, but some of the varieties have flowers of soft and delicate shades which cannot fail to please. The ease with which the plants can be propagated and cultivated may also have added to their popularity. Yet there is much joy to be had in passing a well filled stage of semi-double-flowered plants, when all are in bloom. Geraniums are not only floriferous, but they are charmingly suited as dwelling-house plants and are excellent as cut flowers, having fine shaped heads borne on long clean straight stems. The plants are also well adapted for clothing high walls in the glasshouses, and when grown in such positions they flower profusely and so provide a plentiful supply for cutting. Greenhouse geraniums, unlike their near neighbours the Regal and scented-leaved pelargoniums, are seldom troubled by insect pests, and therefore they are plants to be valued and retained.—DAVID ARMSTRONG.

GROWING STANDARD AND SPECIMEN FUCHSIAS.

THE fuchsia is a most useful plant. It may be splendidly grown in a cold greenhouse or in the open border. In the winter-time the plants may be stored in a shed—even in a roomy potting-shed. But usually we find the majority stored in cool vineries and peach-houses. From the store place we should now take all plants, prick the surface of the dry, hard soil in the pots and remove all loosened soil; then place the plants in a warm greenhouse temperature, syringe the branches early every morning and, as soon as new shoots can be seen, prune back the old branches lightly or severely, as the case may be. At this stage, too, the old balls of soil should be reduced, so that it will be possible to re-pot them in pots of similar size, or even smaller. The method is shown in the accompanying sketches. The original size of the ball of soil when removed from the old pot is shown at *a*; it must be reduced to the size shown at *b*, and many large roots, *c*, *c*, *c*, cut off at the double cross



lines. The plant is now ready for re-potting as shown in the lower sketch. The pruning back may be done after the re-potting. The branches are cut back to the double cross lines shown at *d*, *d*, *d*; the other side, *e*, being similarly treated. All standards should be staked, made secure to new stakes at *f*, *f*. The reduction of the old ball of soil will allow the cultivator to re-pot from the pot *g* to a larger one in the early part of the summer. The result of the hard pruning is shown at *h*, many additional shoots growing. Fibrous loam one-third, leaf-soil one third, old mortar rubble and pounded bricks one-third, form a suitable compost. Feed when new roots are plentiful.—GEORGE GARNER.

VEGETABLES

GROWING ONIONS FOR EXHIBITION.

NOW is the time to sow the seed if one intends to try to grow fine bulbs similar to those often seen at exhibitions during the autumn months. There is no reason why an amateur who has a heated greenhouse and a cold frame at his disposal should not be successful. Two of the principal secrets of success are in the preparation of the ground in the autumn, where they are intended to be grown, and obtaining the very best strain of seed.

One of the best varieties to grow is Ailsa Craig, and if the seeds are sown now, strong plants should result when the time comes to plant them in the bed. Onions are very deep rooting, and the ground should be trenched 3ft. deep, burying any rubbish which has accumulated and good farmyard manure, in the bottom of the trench. After the trenching is finished, give the ground a dressing of lime, and leave for the rain to wash in. In February, if the weather is suitable, the ground should be forked over, and about a month before planting, give the ground a dressing of soot, and move the ground again.

In sowing the seed, get some boxes about 4ins. deep and place about an inch of well rotted manure in the bottom, filling with soil passed through a half-inch sieve. Old chrysanthemum soil is excellent; make it firm and sow the seeds singly about 2ins. apart each way, slightly covering with soil. Some growers prefer to sow in a pan, and prick the seedlings off in the boxes, but it means a check to the plants, whereas by sowing the seeds singly, no pricking off is necessary.

After sowing, water with luke-warm water and place in the greenhouse close up to the glass. See that the soil does not become dry. When the seeds have germinated the seedlings must have air on suitable days, otherwise they will become drawn, and a few weeks before planting the boxes should be removed to a cold frame, to harden off the plants. When planting, allow 18ins. between the plants each way, and see that the ground is firm.

From then onwards the culture depends chiefly on keeping the soil moved with the hoe, and once the plants have made a good start, a slight dressing of some approved fertiliser may be given about once a month, watering it in. This will keep the plants on the move. If it can be obtained, the drainings from a farmyard, diluted to the colour of brandy, is one of the finest foods possible.—ALFRED GURR, *Walmer, Kent.*

ONIONS—GOOD KEEPING SORTS.

ON lifting my onions this season, a friend examined some of the largest bulbs, and after pronouncing them fine, said "It is a pity large onions do not keep very well." As a grower of them for many years, I could not share his views, although prepared to admit that certain varieties kept better than others. My own experience with large onions is, that much depends on drying, handling and storing, as to success in keeping. It is unwise to leave them too long on the bed when weather conditions are not favourable, but arrangements should be made to dry them under cover. Bruising the bulbs, I am convinced, is the chief reason why onions—small as well as large—do not keep. They require handling very carefully, and are best stored, as one would choice apples, in single layers, and if possible, with space between each. I have stored weighty bulbs of Ailsa Craig and Premier in this fashion which have kept us supplied until well into spring. I acknowledge the excellent lasting power of that good old sort, James's Long Keeping, but I am satisfied that to say large bulbs do not keep very well is a mistake, and where failures occur, they may generally be traced to insufficient ripening or bad storing. When it is known that some of them lack firmness, such bulbs should be used first. In any case, examination ought to be made from time to time, and any bulbs showing signs of decay removed.—CLAREMONT.

VEGETABLES FOR THE SMALL GARDEN.

THE small garden that I am now referring to is the one usually found behind the dwelling house and flower garden in towns and their suburbs. Such gardens are being formed in great numbers every year and many owners or occupiers of them are inexperienced in the management, though they have to be responsible for the ordering of seeds and plants. This is not a light task to some persons, while it is a pleasure to others. If things go wrong the seedsman is often blamed while the fault lies in ordering unsuitable seeds to begin with. With the exception of a few rows of very early potatoes, I would not grow the latter in a small garden, but devote the space to other vegetables. Peas, Dwarf gem and Little Marvel, Laxtonian and Gradus will yield pecks of pods and the plants will not occupy much ground. Furthermore, the plants require the minimum of support, an important item in a town garden. A few seeds of Little Marvel may be sown about mid-February. Of broad beans, Beck's Little Gem may be sown in January, always, of course, if the soil is in fit condition. This is a small bean, but a big cropper; then sow Broad Windsor and follow with a row of Seville Giant Long Pod late in March. Hollow Crown parsnip, Rousham Park Hero onion, Little Gem carrot may be sown in February and March, and Intermediate carrot and Market Favourite beet in April; Canadian Wonder dwarf bean in May, also a row of Prizewinner or Scarlet Emperor runner beans. In boxes or pots in a frame sow a pinch each of celery Standard Bearer, cucumber Stockwood Ridge, vegetable marrow Long White. Sow cabbage and cos lettuces thinly outside, also a few turnips and radishes. Buy in May a few tomato plants and from these few kinds, grown in limited quantity, a really fine lot of produce will result.—CHRISTCHURCH.

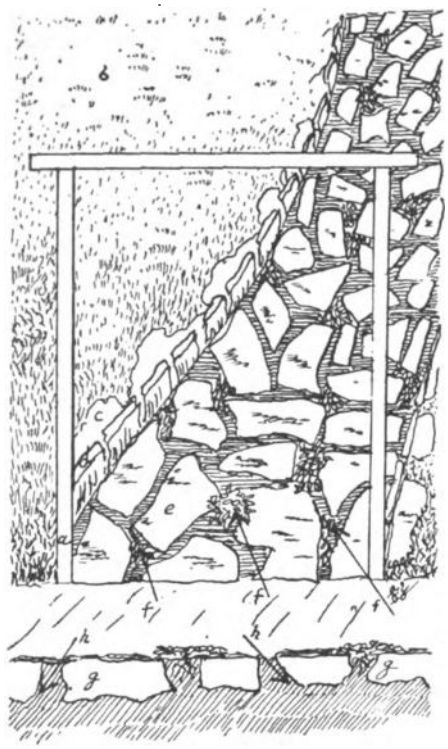
LEEKS: A VEGETABLE SOMETIMES INDIFFERENTLY GROWN.

CONSIDERING their value for the table, and comparatively easy culture, and their immunity from pests to which some other vegetables are subject, it is somewhat difficult to understand why so many who grow leeks are content to do so in a half-hearted manner. It is common knowledge that, among gardeners, one finds those who take a delight in specialising in certain vegetables and wax enthusiastic over them. One comes across this demonstrated in the exhibition arena; but leeks, to the average gardener, call for no special attention, and it is seldom that any extra effort is made to produce weighty specimens; indeed, I go further than this, and say that many sow seed too late, plant them in ill prepared ground, often relegating them to a position not deemed good enough for anything else. In a word, the treatment meted out to them is anything but generous, and, as a consequence of all this, only poor crops result. Having regard to the extreme hardiness of leeks—for frost seldom harms them—it is unfortunate that more who take up their culture do not give them first-class treatment, as scarcely any winter vegetable gives a better return for labour expended. Many start with seed sowing in March, or even April, and so from the first are handicapped, instead of beginning under glass weeks earlier. That great cultivator of vegetables—perhaps the greatest of our time—Mr. Edwin Beckett, has laid it down as an axiom that leeks require a long season of growth and a long period of blanching, and he has followed this up by producing and exhibiting at Shrewsbury, Southport and elsewhere, specimens the like of which has seldom, if ever, been equalled, much less excelled. It is just as profitable for the owner of a moderate-sized garden to do them well, instead of, as is frequently seen, planting them out in ill-prepared ground, with little subsequent attention in the way of feeding.—W. LINDERS LEA.

MISCELLANEOUS

CRAZY PAVING.

PATHS formed of flat stones irregular in size and shape and irregularly laid find much favour in many gardens in these days. Such paths are pleasant to walk upon and very interesting, too, if suitable plants are grown on them and at the sides. But the position should be suitable for paths of this kind; furthermore, the stones should be properly laid. Where the original soil is firm, little basal preparation is necessary for the stones, but where it is soft or liable to become so in showery weather a small quantity of concrete placed under each stone will keep the latter in position. Small



gravel, four parts; cement, one part, will combine to form the concrete. A spadeful neatly placed under each stone slab will help to keep the stones firmly in positions. The spaces between the stones may be arranged just the same as when concrete is not used, and the latter does not interfere with the growth of any tiny plants. The stones must be laid and levelled on the concrete while the latter is fresh. At *a* is shown how arches or pergolas may be built to span such paths. Grass or border is shown at *b*; if grass, small beds irregular in shape may be filled with suitable small plants at *c*, and edges of stones at *d* will be in keeping with the stone path, *e*. Tufts of plants—sweet thyme, etc.—are shown at *f*, *f*, *f*. The section of stones, soil and the roots of the plants are shown at *g*, *g*, and *h*, *h*, respectively.

RUBBISH HEAPS.

IT is not possible to avoid having a certain quantity of rubbish in a garden after a few crops have matured. During a journey of several miles through country, town and suburb, I have seen many rubbish heaps in gardens. Some of the heaps were visible from the public road—they ought not to be so placed—but the majority were in the farthest corners of the gardens. One head-gardener told me that he was dependent upon such heaps of refuse for organic matter for the benefit of his crops of vegetables, as farmyard manure was not available. He grew excellent crops of runner beans with the aid of decomposed weeds, crop refuse and tree leaves. Personally, I make a point of collecting such refuse and storing it in "dug-outs"—holes in a suitable corner, putting salt and lime on it and turning the heap from time to time. Every spring there is a nice quantity of rotted rubbish, mixed with ordinary garden soil, available for the various vegetable crops. If such heaps are kept lightly covered with earth, they are not unsightly; and if they are treated as here described, the contents is not offensive. All hard wood, twigs and stems of cabbages, cauliflowers and other kinds of greens are burned with ordinary garden soil and hedge trimmings. The treated refuse and the ashes and burned soil form a valuable manure, and nearly every gardener may command small or large quantities.—G. G.

SCALE ON PLANTS AND FRUIT TREES.

QUESTION.—Are the brown scales seen on peach and nectarine trees and many pot plants dead when found during the winter months?

Answer.—The brown scales are full of eggs or young scales, the latter can be seen with the naked eye quite plainly when the old scale is broken, and, under a powerful glass they look quite formidable. If left undisturbed many thousands of young scales will be found on the young branches in spring.

Question.—When and how should the scale be destroyed?

Answer.—If possible, they should be eradicated while the trees—in the case of fruit trees—are inactive. The wood is harder and insecticides may be safely used at their full strength. But it is always wise to keep all washes, applied by hand with sponge or brush, off the buds. Furthermore, while the trees are leafless, it is possible to see every bit of twig and bark. Whether it is a plant in a pot or a fruit tree, begin at the top and finish at the bottom. Do not use a knife, but a tiny piece of hard wood pointed, or a piece of sharpened bone. Use the point to eradicate the insects from the axils of buds and branch, or branches. Brush all scales found, loosening them on the bark. Sponge them off, using insecticides for the purpose as advertised in THE GARDEN. Before the washes dry, vigorously syringe the branches from two points and then remove any surface soil on which the pests may fall.—HANTS.

THE HARDY PLANT BORDER.

ALTHOUGH the plants generally are dormant during the mid-winter months, every root and cut-back stalk has an interest for the lover of these plants. One need not worry much about the plants themselves, however severe the weather may be, as such will cause the roots to take a thorough rest and, in due course, the fresh growth will be very robust. But, when we find the soil in a suitable condition to be dealt with without any adhering to boots and tools, we should loosen the ground between the clumps of plants as deeply as we can without disturbing any roots. Some rotted manure, wood ashes, leaf-soil and thoroughly decayed vegetable refuse may be incorporated in the soil at the same time. When we pause to think about the huge masses of stems, foliage and flowers in our herbaceous beds during the summer months—and we all have visions of them in dreary mid-winter—we should realise the fact that such growth cannot be maintained unless we feed the roots.

RHODODENDRON SHOW

WE have pleasure in publishing the Schedule of the Rhododendron Society's first show, to be held at the Royal Horticultural Hall, Vincent Square, London, S.W.1, on Tuesday, April 27th, 1926.

1 Best group of rhododendrons shown by a trade exhibitor. Challenge cup and silver gilt medal.
2 Best group of rhododendrons shown by an amateur. (Attention is called to the fact that rhododendrons may be shown either cut or on plants and either grown in the open or under glass.) Challenge cup and silver gilt medal.
3 Twelve species, distinct, single truss of each.
4 Twelve hybrids, single truss of each. (Not more than three and only distinct seedlings of the same cross may be shown.)
5 Three species, distinct, single truss of each.
6 Three hybrids, not of identical parentage, single truss of each.
7 Best species, one truss.
8 Best hybrid, one truss.
9 One truss of Falconeri.
10 One truss of Wightii.
11 One truss of argentum or grande.
12 One truss of calophytum.
13 One truss of lacteum.
14 One truss of fictolacteum.
15 One truss of Aucklandii or Griffithianum.
16 One truss of arboreum, blood red.
17 One truss of arboreum, any other colour.
18 One truss of niveum.
19 One truss of campanulatum.
20 One truss of Fortunei, Houlstonii or any form of decorum.
21 One truss of Davidii, Fargesii, haematocheilum, orbiculare or oreodoxa.
22 One truss of pachytrichum or strigillosum.
23 One truss of campylocarpum, croceum or Wardii.
24 One truss of Thomsonii.
25 One truss of haematodes or sperabile.
26 One truss of neriiflorum.
27 One spray, not exceeding 18ins. from the top of the vase, of rubiginosum.
28 One spray, not exceeding 18ins. from the top of the vase, of Augustinii.
29 One spray, not exceeding 18ins. from the top of the vase, of chartophyllum, Davidsonianum or yunnanense.
30 One spray of a Chinese or Himalayan alpine species, not exceeding 8ins. in diameter or 15ins. in height, of a mauve or purple colouring.
31 One spray of a Chinese or Himalayan alpine species, not exceeding 8ins. in diameter or 15ins. in height, of a yellow colouring.
32 One spray of a Chinese or Himalayan alpine species, not exceeding 8ins. in diameter or 15ins. in height, of pink or white colouring.
33 One truss of Dalhousiæ, Lindleyi or Nuttallii or their hybrids.
34 One spray, not exceeding 18ins. above the top of the vase, of any other sweet-scented species or hybrid.
35 One spray, not exceeding 18ins. in height above the top of the vase, of any deciduous rhododendron species (azalea included).
36 One spray, not exceeding 18ins. in height above the top of the vase, of any deciduous rhododendron hybrid (azalea included.)
37 One spray, not exceeding 18ins. in diameter or 15ins. in height of an evergreen azalea.
38 Single truss of any large-leaved hybrid (such as Elsae, etc.).
39 Single truss of any hybrid between Aucklandii and a species.
40 Single truss of any hybrid between Aucklandii and a hybrid.
41 Single truss of any Thomsonii hybrid.
42 Single truss of any campylocarpum hybrid.
43 A spray of any cinnabarium hybrid, not to exceed 18ins. above the top of the vase.
44 Six hybrid rhododendrons lifted from the ground or grown in pots, not to cover more than 60ft. super.
45 Three alpine rhododendrons lifted from the ground or grown in pots.
46 Six distinct trusses of "Hardy Hybrids" in commerce.
47 Six vases of evergreen shrubs or trees in flower suitable for growing with rhododendrons.
48 Six vases of deciduous shrubs or trees in flower, suitable for growing with rhododendrons.

A special prize is being presented by Mr. E. H. Wilding for the best plant of rhododendron exhibited.

Entry forms and full copies of schedules and regulations may be obtained from the Secretary, R.H.S.

We hope that all rhododendron enthusiasts, and they are many, will exhibit at the show.

BOOK REVIEW

STRANGELY enough, in the number of books devoted to various aspects of horticulture, there is none which deals solely with the scent of flowers, and the little publication which has come into our hands, "Flower Scent," by F. A. Hampton, M.A., M.B.Ch.B., published by Messrs. Dulau and Co., price 6s., is all the more interesting on that account. The author has attempted to gather together the threads of work by various authorities on the subject, and has successfully presented them in a simple and coherent whole, supplemented by personal experience and observation.

The subject is a wide and intricate one, being closely bound up in the sciences of chemistry and botany, and it is creditable that the author has reduced technicalities to as simple a form as possible while still retaining a proper proportion and balance. In such a form the subject is of general interest. On the one hand, the perfumer and chemist will find it of great service in their everyday duties; while on the other, it presents to the botanist and gardener many interesting facts on this fascinating floral character.

Although small in size, the book covers a wide field. The purely physiological introduction may not be considered necessary by some, but it undoubtedly leads to a better appreciation and understanding of the later chapters, more especially when the subject is new to the reader. In the subsequent chapters, the composition and development of scent, although highly technical, is successfully negotiated in simple and direct language and, indeed, is made to be positively interesting. The next four chapters are more or less of a botanical nature, treating of the distribution of essential oils in the plant, the function of scent, the correlation which exists between the insect and the flower world, and scent in relation to botanical character. Again, the author is to be congratulated on the way he presents his facts. More might have been said on the subject of insects in their relation to the scent of flowers, as undoubtedly that remains as one of the most interesting features of botanical physiology and morphology, but the reader who wishes to probe still further in the mystery will find the short bibliographies given at the close of each chapter of extreme service.

One of the chief points of interest in the book is the classification of flower scents, which the author puts forward based on one arranged in 1893 by an Austrian botanist. The scents are split up into various groups, such as the rose and violet groups, and a detailed examination is made of each. Although the author claims that it is only a tentative scheme, it should prove of extreme value and service to those who are keenly interested in the subject.

Of more general interest is the chapter on our appreciation of scent, where the author drifts into psychology. One or two conclusions which he reaches are indeed stimulating and may perhaps suggest to the reader a new line of thought. Unlike other writers on the subject, he concludes that "a sweet scent is one that can stir the instinct of courtship without evoking the idea of the natural end object of the instinct."

To the gardener much of interest and instruction will be found under the heading of "Scent in the Garden." The author is well qualified to speak on the subject, and the lists of scented plants which he has compiled will greatly assist those who wish for fragrance in the garden. Rose lovers will also find a useful classified list of fragrant roses which are in general cultivation, and they need have no hesitation in following the list faithfully, as it has been arranged by Mrs. H. R. Darlington. In the chapter on "Extraction of Scent" many hints are given to those who would prepare their own perfumes at home. The last chapter, on the "History of Scent," is both interesting and instructive, and the appendices already referred to are of the greatest value, representing much patient study and research on the part of the author.

The author shows a wide knowledge of his subject, as is exemplified by his treatment and presentation of the facts in the most simple and lucid of literary styles, which serves to sustain the interest of the reader from the first to the last page.

It is a little book which fills a niche in our horticultural and, indeed, in our general literature, and all gardeners, and more especially those interested in fragrance in the garden, would be well advised to read through its pages.

TRADE NOTE

All sweet pea enthusiasts will be interested to hear of the valuable work in connection with the improvement of this popular flower which is being carried on by the sweet pea specialists, Messrs. Carter and Co. of Raynes Park. For a number of years this firm has grown vast quantities of sweet peas annually, and each year they save seed from only such varieties as are good in colour and form, robust in constitution, and are not liable to be scorched badly by the sun or spoilt by rain. This season, for selection purposes, over six hundred rows of sweet peas were grown in their trial grounds at Raynes Park, and in their seed catalogue they list as many as two hundred named varieties, among which are thirteen novelties for 1926. These varieties include some of the best sweet peas of every shade which are suitable for either general decoration or for exhibition purposes.

CATALOGUE RECEIVED.

Mr. W. J. Unwin, Histon, Cambridge, the well known sweet pea raiser, sends us his catalogue of sweet peas, flower and vegetable seeds, gladioli, dahlias, roses, etc. Many fine sweet pea novelties and the best of the modern gladioli varieties are included.

FOGWILLS WONDER LONG-POD BROAD BEANS

Ten Beans in a Pod.

WONDERFUL FREE GIFTS.

NOW IS THE TIME TO SOW FOGWILLS WONDER LONG POD. The LONGEST, most PROLIFIC and FINEST FLAVOURED BROAD BEAN in the World. Nothing like it. Nothing just as good—PERFECTION. 1/4 per pint, carriage paid. Send now; every customer will receive three FREE GIFTS as follows—1/- packet (2,000 seeds) FOGWILLS FAMOUS GIANT EXHIBITION BRUSSELS SPROUTS, largest, most magnificent solid sprouts in cultivation, and FREE, a 6d. packet (1,000 seeds) FOGWILLS PRIDE OF THE VALLEY PARSNIP grown over 50 inches long, and FREE one packet (100 seeds) FOGWILLS GIANT RAINBOW SWEET PEAS, large waved flowers in over 25 shades. Send only 1/4 for this wonderful FREE OFFER and become one of our THOUSANDS of satisfied customers.

Fogwills 'Best-Result' Seeds need only a trial.

Fogwills Beautiful Illustrated Catalogue of "Best-Result" Seeds and Guide to Garden Success for Season 1926. Now Ready. Post Free.

FOGWILLS, Established 70 years. 130, FRIARY STREET GUILDFORD. Awarded Gold Medal.

ANNUALS AS POT PLANTS

IN most establishments to-day the stove and warm greenhouse plants have disappeared, and their place is taken by others that are less costly to produce and require little fire heat. There are a large number of annuals suitable for our purpose.

Among the most prominent will be found the clarkias of the elegans class. One of the best is Scarlet Beauty, a really fine salmon-scarlet, the flowers being double and produced in long sprays. There are other forms of clarkia, such as Firefly and Salmon Queen, but the one quoted above is the best I have seen for pot work.

Flowering stocks are indispensable, particularly in winter and spring and if suitable varieties are chosen and the

plants never allowed to become starved in the young stage a fine display can be secured from specimens in 5in. pots. All the Year Round is a fine white-flowered stock with wallflower-leaved foliage. It is dwarf and very vigorous. Christmas Pink is also a noteworthy acquisition. The Beauty of Nice group can be strongly recommended. They have a fine branching habit and attain a height of 2ft. Old Rose is especially attractive as a pot plant, and other shades are to be obtained; such as white, mauve, crimson and pink.

For a really fine display of various coloured flowers the schizanthus are well to the fore, and the dwarf hybrids are well adapted for the small greenhouse. There are several noted strains in existence, especially of the hybrid and wisetonensis type, while the retusus forms

Please mention THE GARDEN *when writing.*

deserve to be more widely grown. The first sowing is made in January, but another sowing can take place in August for winter display.

Gilia coronopifolia, a half-hardy biennial must be included. It attains a height of 3ft. to 4ft., fine larkspur like foliage, and long spikes and branchlets of brilliant scarlet crimson flowers.

The salpiglossis are pretty ornamental annuals with large-veined, funnel-shaped flowers, the plants reaching a height of 2ft. to 3ft.,

The sweet scabious is offered in various colours and mixed, and they are most attractive for the greenhouse, and will no doubt in time be largely employed for this purpose when their value is more fully realised.

Mignonette is always a favourite, but for some reason the fine pots seen at Covent Garden Market are not met with in private gardens. The seed is sown in the pots in which the plants

will bloom, and three or four seedlings will be enough for a 5in. pot.

With the exception of mignonette the seedlings are potted off singly as soon as possible, and when established the schizanthus and clarkias must be pinched to encourage the formation of side growths. The next stage will be the final potting in pots 5ins. and 6ins. in diameter. The compost consists of good quality fibrous loam three parts and one part leaf-mould, and manure from an old mushroom-bed.

Other annuals will occur to the observant grower, but the culture is on similar lines. The keynote throughout their career is cool treatment, and one of the principal factors in their successful cultivation is judicious ventilation to prevent the damping off of the foliage. No amateur or beginner need fear growing the plants mentioned in these notes, and few greenhouse subjects give such a generous return for such a modest outlay.

T. W. BRISCOE.

UNWIN'S SWEET PEAS

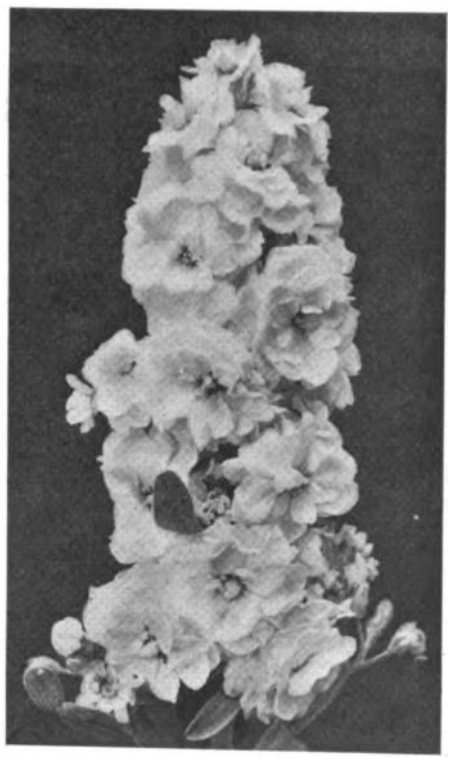
STOCKS ALL THE YEAR

ALTHOUGH we think that the stocks are not so popular as they used to be, yet in many gardens they are always favourites on account of their delightful fragrance and the beauty of their flowers. There are many varieties now available in the three "divisions," into which this flower is placed, and those who love them can have their favourite blossom throughout the greater part of the year.

The summer-flowering or ten-week stocks are well known to all. Raised under cool conditions in spring and planted out in May, they are in flower by the end of June; in good soil, where they can be grown fast without a check, and always with the provision that a good strain of seed is obtained, they are a delight throughout the summer. Many fine varieties can be had, tall and dwarf; ordinary bedding sorts, in colours, are charming, but we might mention the dwarf, large-flowering strain in particular. For cutting Snowdon, Canary Yellow, Blood Red,



Vesuvius and other tall, unnamed colours are exceedingly fine.

The East Lothian or intermediate class is later in flowering, from sowings made as early as February, but they come into grace when the others are losing their freshness, and, being very hardy, continue to please for a long time. Covent Garden is an old favourite here, but there is a lack of named varieties and one has to be content with colours; the plants branch more than the former varieties and need more space when planted out.

The late autumn, winter and early spring being an "off" season, as far as outside bloom is concerned, it is necessary to grow stocks for flowering in pots in a cool or temperate house. The plants do not need much heat; the compost ought to be mainly a good turfy loam, and such feeding as is given ought to be delayed until the flowers are about to appear. When in the seedling stage care must be taken to see that they are not checked in any way, nor over watered, and as they flower they must have space to look their best. Opinions will differ, undoubtedly, as to the best kinds; I personally prefer the "Beauty" series, and generally grow a few of each of the six colours. The Emperor varieties—Crimson King, Elizabeth and White Lady—are also very fine.

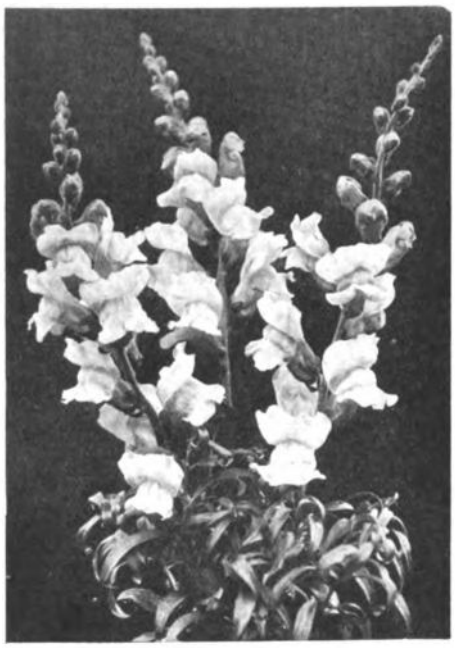
ANTIRRHINUMS FOR GAIETY

OUR title, perhaps, in its brevity strikes the most forcible note, for none can deny that there is soundness in the judgment which selects antirrhinums for gaiety.

The colour chart that should embrace every brilliant hue and subtle tint to be found in a representative collection of antirrhinums would be no simple production, but concise and accurate description of many of the shades would be beyond the power of pen. Blue alone is lacking, but of all other colours there are graduated shades and delightful combinations.

There are varieties varying from delicate pink to deep velvety crimson. The apricot and lemon shades are also most attractive. For bedding, the glowing orange scarlets, such as Orange King and Fire King, and the bright pink Nelrose, produce a very striking effect. These intermediate varieties are more



suitable for massing than the tall strains of antirrhinums. Buff-pink, creamed tinged with pink, white with pink markings, chocolate maroon and such colour combination as crimson and gold, are a few of the delightful and uncommon shades which are to be found among the modern antirrhinums.

About three years ago a variety named Radiance made a well deserved name for itself, for it was a compelling flower of exceptional brilliance; but, alas! it cast itself upon the rock which has wrecked many a flower, for it proved unsteadfast and unfixed in colour. Many who followed the strong recommendation of enthusiasts found Radiance from seed a failure, but there is hope yet that a sound stock of this intensely brilliant flower will soon again be forthcoming. Meanwhile if any growers find indifferent stocks of so good an antirrhinum it is sheer folly to distribute them, for the injury is not confined to it alone, but adversely affects the advancement of the whole cult of the antirrhinum.

£300 in Awards for Raising "Hollyhock" Delphinium Seeds

WITH a view to securing the interest and co-operation of amateurs, BEES LTD. have reserved £300, to be given in awards to raisers of new, and improved, varieties of "Hollyhock" Delphiniums.

A free packet (3 seeds) saved from the better varieties of this magnificent strain, together with Bees' Seed Catalogue, will be sent to each person who remits 6d. for the following sample packets:—

Mixed Godetia - 1,000 seeds
Love-in-a-Mist - 200 ,,
Double Clarkia - 1,000 ,,

Larger packets of "Hollyhock" Delphinium Seeds may be obtained at 2/6 per packet; three times the quantity for 5/-

Remember! any one seed may win an award.

Detailed instructions upon raising, and full particulars of the scheme sent with the seeds.

NOTES ON TREES AND SHRUBS IN SCOTLAND

I JOURNEYED up to my home the other day to see what damage 9ins. of snow and 22 degrees of frost had done to the shrubs and young trees. I found them all unscathed with the exception of Panax arborea, of which both leaders had bent over under the weight of snow; but even this reputed half-hardy shrub seems otherwise to be unharmed. It may be imagination, but this long spell of cold weather, which has continued with hardly a break for over six weeks, seems to have done good already; it appears to have ripened the wood in a way that has been lacking in the two previous seasons, and the bark of many things is certainly harder and healthier than it was at this time last year. The frost has also shown up beauties that I had not seen before. Viburnum fragrans, although the flowers were browned by the severest frost, is scaling its bark in the same way as some of the birches, and is showing a vision of various tones of russet mahogany that it certainly never had with me before; while a form of Philadelphus coronarius that Farrer and I found in Burma is forming a distinct striation in its old wood that was certainly absent last year. Incidentally, this has appeared just in time, for, so far, it has run to wood and not to flower, and if it had not been for this improvement it would have been relegated to the dust-bin. Now it has been reprieved for a year, and I have cut it back vigorously in the hope of flower, for I remember it as a fine thing with pearl white flowers the size of half a crown. This weather has been ample test for Hamamelis mollis and H. japonica. I noticed early in November that they were crammed with flower buds. They are now slowly bursting, and 10 per cent. of the buds are showing butter yellow at their tips, while careful examination has not shown a single damaged bud. My plants are now 3ft. to 4ft. in height, and it is only this year that I have noticed their extremely shapely and distinctive growth that reminds one of Viburnum tomentosum Mariesii, only squatter and without the perpendicular central stem that is such a feature of the latter plant.

Another precocious plant that I am surprised is so successful is Spiræa sorbifolia, for this year it appears to be tired of the long spell of cold and is already sending out tiny tentative shoots of green that seem to relish the cold. Although it is over 6ft. high it has not condescended to flower with me yet, and I have had it for six years. It may be more vigorous than the common form, but by now it should have been showing signs; it also has been cut back severely in the hopes of making it flower, but it has not shown its habit of suckering that Mr. Bean writes about.

Two or three years ago I began to collect birches, and with some trepidation, for ours is not a birch country where they seed themselves freely. The result, however, has been well worth the attempt, for after the first year they have taken to this soil in a very kindly fashion, and I can bear out fully what Mr. Wilson has been saying lately in THE GARDEN about their beauty and interest. In my opinion, they are first and foremost of all trees for the garden that have no pre-eminent flowering qualities. The fastest grower and best here is a birch of Forrest's called Betula Delavayi var. Forrestii, which is commonly called the Tibetan red birch. Although only 6ft. high they are already showing the vivid old-red tinge of the bark. These in speed of growth are quickly followed by B. Ermanni with a creamy white bark and B. albo-sinensis, a great treasure and very rare with white bark; but after all I doubt if any of them can beat our own silver birch when well grown. Betula Schmidtii on the other hand, is very slow and, as Mr. Wilson points out, is often inclined to make a shrubby growth, although in its native home in Korea it is a tree of some 60ft. I have a number of seedlings coming on of B. nigra papyrifera and other American birches, but they are not large enough yet to tell how they will do in this East Coast climate.

Although ericaceous plants do well considering the dry, cold climate, those of the genus pieris do not take at all kindly to what I can give them. They should be as hardy as many other plants that I have, but I have failed with the usual P. floribunda and P. japonica, while even seedlings indoors of the rarer P. taiwanensis and P. formosa are miffy plants. I should be much obliged for information upon the needs of this genus, for they are among the most beautiful of all flowering shrubs with their racemes of white bells and elegant growth.

As a whole, this hard winter has been a blessing to most plants and, if only given reasonable spring weather, I look forward to a very fine flowering season ahead. E. H. M. C.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

SOME ANNUALS OF DISTINCTION, by A. T. Johnson.

PLUMS AND CHERRIES, by A. J. Cobb.

NOTES ON A ROCK GARDEN, by F. Dysart.

Digitized by Google

PERENNIALS FROM SEED

MANY OF THE FINEST PERENNIALS THAT ARE TO SEEN IN OUR GARDENS ARE THE PROGENY OF CHANCE SEEDLINGS. MR. GIBSON DESCRIBES A FEW KINDS THAT ARE WORTH GROWING FROM SEED.

THERE is but small inducement to the owner of the little garden whose area is measured in feet and inches to grow from seed the plants of perennial habit which appeal to him. Having room for only one, three or half a dozen plants of a kind, it behoves him to pay the price of more immediate results by purchase from a nursery. Yet, tiny indeed would the flower space be that could not afford the pleasure of raising say a few pansies, violas or polyanthuses from seed.

The idea of growing plants from seed in quantity where they are required or desirable has its origin in two divergent stimuli, one from a sense of economy and the other of peradventure. The former is sternly practical, though its objects may be purely ornamental, the latter enterprising, but fortuitous, though *its* aim may be utilitarian. The economical process usually deals with types that come true or nearly so from seed, otherwise the purpose would miscarry. Thus, to design into a large garden an extensive mass of blue in tall plants, one packet of anchusa or delphinium seed, costing perhaps a couple of shillings, will accomplish the same end as the investment of, may be, a hundred times that amount for as many plants of named varieties, with the additional gain of seedling vigour against some weakness or uncertainty among propagated plants. Where spaces are generous and much planting must be done to fill large beds or borders, many uses can be found for seedlings of perennials, such as replenishing ill-faring patches in borders, furnishing pockets of the rockery, supplying colour to the kitchen garden, naturalising by waterside, alpine meadow or woodland. In pursuing such ends, stimulus number two, that of enterprise and perchance, is often blended with the first. A whole packet of aubrietia seed may be sown to hit on the right shade of purple for a favourite spot on the rock garden, where perhaps only a dozen plants are required, or a lawn bed may be filled with seedling carnations or dahlias to serve a double purpose, first as a foil of high colour to the surrounding verdure, and secondly as a testing ground for novelties.

I call to mind two excellent examples of the different motives suggested in raising large numbers of plants from seed. For the last three years a lady in California has sent to us for such a large number of packets of delphinium seed that we could not but wonder what her garden was like or what the purpose. Last spring she sent us a photograph of her estate, evidently running into many acres, and explained that she had been planting a mountainside with the delphinium seedlings in wider area each year, and that they had naturalised so happily that this extraordinary sheet of blue was the mecca of flower lovers for miles around. That seems to me a very pretty conceit—think of four or five thousand delphinium plants raising their tall spires of azure against the sloping hillside in a lovely landscape of timbered valley and rocky hill crest! And such munificent lavishness in planting was conjured up at the cost of some ten or twelve dollars.

MANY FINE HYBRID TORCH LILIES HAVE BEEN RAISED BY AMATEURS.

The other example is that of Mr. G. D. Murray of Worcester Park, the renowned amateur carnation grower. He grows something like an average of 10,000 seedlings a year, makes his garden beautiful each summer and attracts hosts of visitors, but his real aim is a sedulous quest after something new or better than what has come before. And the people know his keen eye has sought out many a wonderful flower with which he has enriched the carnation world. This is a typical example of sowing and planting in the spirit of adventure, hazard and enterprise.

SEEDLING PERENNIALS ARE ALWAYS A SOURCE OF INTEREST TO THE KEEN GARDENER.

Digitized by Google

Here are a few perennial plants which offer some especial interest when grown from seed, with simple cultural hints.

AQUILEGIA.—Sow in latter part of March or in April in a frame or prepared bed in a partially shaded site, prick out when seedlings are large enough to handle, and transplant later to flowering quarters, where they will bloom in June and July of the following year. A good strain of seed will allow of a free selection of choice varieties which are increased by root division. Grow in semi shade.

ASTER (Michaelmas Daisy).—Seed may be sown any time in spring or early summer, the seedlings pricked out into a nursery bed for the summer and transplanted in autumn to their permanent stations. The cordifolius, ericoides and Novi Belgii give, perhaps, the most interesting results, the two former providing graceful bush plants with a myriad of small flowers, the last a wide range of colour in large blooms.

AUBRIETIA. — Sow in spring in pots or pans in cold house or in a frame. If sown thinly the seedlings may remain untransplanted until the first flowers show, which they will do on quite small plants, when a selection of the best colours may be made and the poor ones thrown away. Seedlings from any of the newer hybrids will give an extensive range of colours in lavender, purple, rose and violet. Sunny aspect.

CARNATION. — April is soon enough to sow, as the plants should not be too large when placed in their flowering quarters in June or July. As the seed is fairly large it may be sown widely, say an inch apart and 2ins. between the rows. This obviates pricking out. The seedlings should remain under glass, but with abundant ventilation till planted out, as this is a fairly effective means of thwarting the fly responsible for the carnation maggot. A good strain of seed will give many lovely flowers with a good chance of securing something novel and valuable. Firm planting, sunny position and a calcareous soil are the main elements of success.

DELPHINIUM. — Easily raised by sowing in boxes or a frame bed. Treat as for carnations if wanted to flower the following year, but good autumn spikes can be obtained by sowing in heat in February or March and planting out as soon as large enough. If best seed only is used it is almost sure to reward the grower with many plants of high excellence.

GLADIOLUS.—So long as it was believed that this plant required from three to five years to reach flowering size there was no demand for seed, naturally enough. Now that it has been amply demonstrated that some of the seedlings can be flowered within seven months from sowing, and that abundant bloom is quite natural in the second year, a great impetus has been given to the raising of seedlings and many new and extremely fine hybrids are being raised by amateurs. To me this is probably the most fascinating of all plants to grow from seed. Sow in deep boxes of rich soil with an inch of light sandy material at the top. If artificial heat is available a start can be made about the end of January. If cold frame only is available, about mid-April is a good time to sow, but in that case no flowers need be looked for the first season. Do not transplant or disturb the roots in any form during the first year's growth.

IRIS SIBIRICA.—This plant is easily raised from seed. Sow in the open in shallow drills in spring and transplant in October or November to flowering quarters. Very pretty flowers are obtained by sowing seed of the type, and the newer hybrids such as Snow Queen, Nora Distin, Perry's Blue, Kingfisher Blue and Emperor.

A GRACEFUL LONG-SPURRED AQUILEGIA.

KNIPHOFIA.—Some years ago I obtained some kniphofia seed from the annual distribution of the Wisley surplus and raised some beautiful red hot pokers therefrom. Having no time for such pleasantries now I can yet recommend them to others. Sow in pans or boxes in light, porous soil, during April and May. Growth at first is very slow, but when transplanted out of doors in fairly rich soil, rapid progress is made and the plants flower well the following year. Good drainage and a warm, sunny position should be chosen.

LILY.—Many of the lilies are quite easily grown from seed, but a few recommend themselves especially, not only because of easy culture, nor only on account of their extreme elegance and utility in the garden, but because, wedded to these virtues they have the additional one of speedy results. Lilium Regale, L. philippinense, L. formosanum, and L. Sulphur-gale are typical examples of these easy tempered liliaceæ.

Lily seeds are large enough to sow individually and they should be placed widely enough to obviate pricking out in the very early stages of growth. Boxes or pans are suitable for sowing in and the compost should be about equal parts of fine loam, leaf-mould and silver sand. It is worth while potting up the seedlings singly in small pots and later on transferring them to larger ones as required. This does away almost entirely with root disturbance, a performance of which the lily is rather impatient. Well grown seedlings will flower the second year. They succeed quite well in a full sun, provided abundance of moisture is available, but partial shade is preferable.

VIOLA.—Seed may be sown in February in slight heat for flowering the same year and in summer for the following spring. Transplant with as little disturbance to the roots as possible and plant in a position lightly shaded from hot sunshine. Either side of an espalier fence running north and south is an ideal position.

J. L. GIBSON.

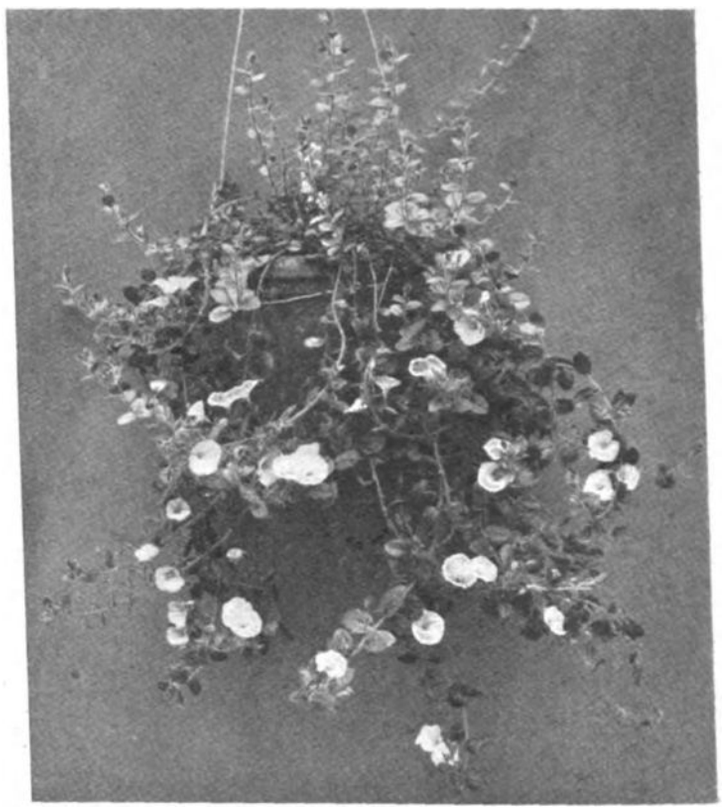
ANNUALS FOR HANGING BASKETS

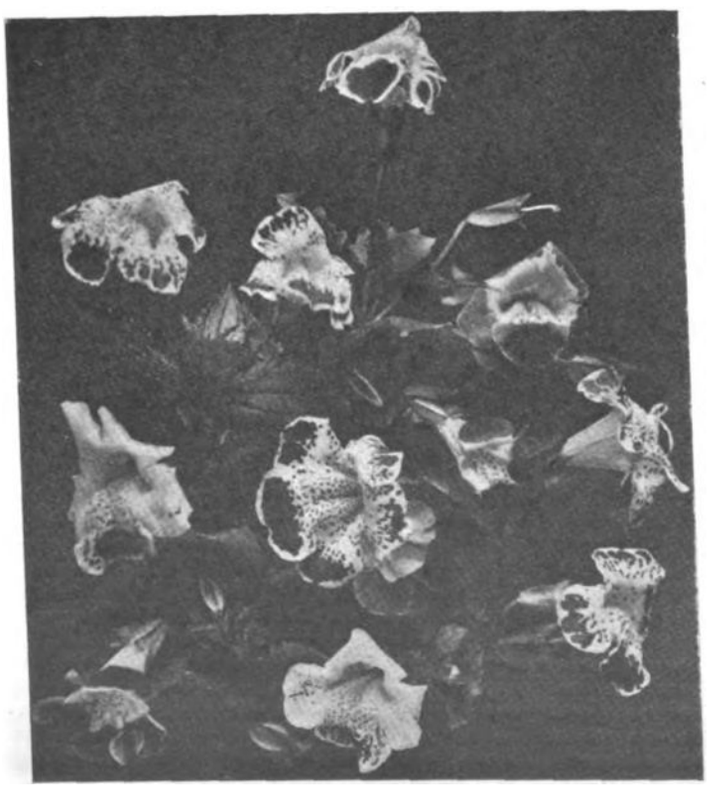
IT would be impossible to over-estimate the debt that we owe to the gardener who first conceived the idea of growing plants in baskets for suspension in either the greenhouse or the many positions where they are so admirably beautiful in the open air during summer and autumn. Picture the veranda, basketed or basketless: imagine the conservatory under similar conditions: and there can be no question as to which presents the more beautiful and charming appearance. There are, of course, certain perennial plants that are so valuable that we can only consider them indispensable—the ivy-leaf geranium, to wit—and these we must have, together with the petunia and other time-honoured favourites.

But this does not exhaust the possibilities, and especially is this true in the direction of annual flowers, for a wealth of really charming and unusual material awaits those who will make use of it and, by setting to work now, we may, this summer obtain some extremely striking results. Take Convolvulus mauritanicus, for example. Here we have a plant that is not difficult to raise from seed, which gives us charming trails of silvery foliage and large violet-blue flowers that are produced in a regular succession. This is most striking where only a cold greenhouse is available or for outdoors during summer and autumn. We have already made mention of the petunia, and, with its gorgeous colour effects, there are few better long-lasting plants that can be chosen for outdoor summer work, especially where the position in which the baskets are hung is a very sunny one.

Equally brilliant is Phlox Drummondii, and this makes wondrously flowerful baskets either when grown in mixture or separate colours. The natural trailing habit is displayed to its fullest advantage and the eye, so striking a feature of some varieties, also shows up well. It is only of recent years that the schizanthus has been used as a basket plant, and those who have not seen or tried it in this way would scarcely credit the extremely decorative baskets that can be obtained. Of course, the seedlings need a good deal of training and tying in order to obtain that perfect ball-like effect, but it is well repaid in the ultimate result and the maze of beautifully marked and coloured blooms. For a warm greenhouse, Torenia Fournieri makes a capital basket plant when planted rather thickly all over the surface (including the sides) and stopped several times before being allowed to flower. Culturally this loves a humid atmosphere, and care should be taken that the basket is suspended well away from any ventilation, etc.,



A WORTHY BASKET PLANT, CONVOLVULUS MAURITANICUS.



THE BRILLIANT MIMULUS MAKES A SPLENDID BASKET ANNUAL.

where it might be exposed to draught. Should a strong blue flower be desired it would be difficult to excel Lobelia Sapphire, a magnificent trailer with masses of clear sapphire flowers, rendered still more conspicuous by the vivid white eye. This is equally good outdoors or under glass, though care must be taken, when hung outdoors, that the soil is abundantly supplied with water.

For large baskets in the conservatory, Coleus Rehmannii provides both flowers and foliage combined in a particularly attractive manner. The growth is of trailing habit, with pretty reddish brown leaves and quantities of light blue flowers. If this is not enough, we may add a still further charm—fragrance of the flowers: while the plant once raised is readily propagated by means of cuttings, rooted in sandy soil. Not so long lived as some things, Venus' Looking Glass forms glorious cascades of widely expanded campanula-like flowers, reddish-violet in the type plant, although there are also lilac and white varieties that are equally desirable. This may either be sown in the soil in the basket, or in a seed-pan and then pricked off, but in the former case it is well to have a few extra seedlings on hand so that these may be inserted into the sides as well as the top. The shamrock pea—Parochetus communis—is rather a rare plant of hardy perennial character that readily flowers the first year if the seedlings are sown early in moderate heat. The habit is trailing and the stems bear clover-like leaves and pretty blue flowers.

The brilliant mimulus, although so dwarf, makes, when thickly planted, a splendid basket annual that succeeds in the most striking manner when hung in a shaded position where few other plants would flower satisfactorily. Care must be taken that these are always well supplied with water, for they are one of the thirstiest of plants. For dense masses of white, Alyssum maritimum is specially good, and Little Dorrit is one of the best. It should not be overlooked that this has now added colour to its other attractions, and Lilac Queen, in pale

Digitized by Google

lilac, is particularly pretty. Abronia umbellata makes lovely baskets of rosy purple flowers with a paler eye, that remain in flower for a very long time and give forth a pleasant fragrance resembling that of honey. Mesembryanthemum tricolor is invaluable for very sunny houses or warm positions outdoors. The sunnier the spot, the more freely and widely do the myriads of daisy-like flowers expand. These, at their best, are a revelation indeed—with vivid rose pink flowers, darker in the centre. Although these plants flourish amazingly in hot, dry situations, we must not forget that, where exposed to the air on all sides, considerable evaporation is taking place, and therefore they should not be permitted to become too dry.

In the general management of basket plants, it is very essential to line out the basket thoroughly with a thick layer of moss—so as to keep the soil from washing through. Next to this, use a fairly rich soil and, by all means, add a little peat to this, so as to asssist in retaining moisture. Get your planting done early, so as to allow the plants to become established before they are hung in the open air. During really hot weather, it is impossible to water by pouring on the surface, and the most satisfactory method is to have a large deep vessel into which the basket may be lowered and allowed to soak for half an hour. One other point to which attention must be paid is their safe suspension. H. W. C. W.

WINTER-FLOWERING BEGONIAS

THE genus begonia is both a large and varied one, and in the decoration of the greenhouse and flower garden they play an important part; moreover, the flowering period is spread over the greater part of the year. One group, however, is not so largely grown as its merits deserve, and this is generally known as the winter-flowering section, although some of the plants could be had in full flower in October if desired. I believe many consider them difficult to cultivate, but this is not really so if care is taken during the resting period and the growths are kept free from rust or mite.

It is interesting to note that one species, Begonia socotrana, is the principal parent of this group of begonias, and this important species was introduced by the late Professor Sir Isaac Bayley Balfour of Edinburgh fame, who sent plants to Kew in 1880. It was discovered in Socotra, a small island off the Arabian coast in the Indian Ocean. It is a dwarf plant with scaly rhizomes, and rose pink blooms nearly 2ins. across. Among the earlier hybrids will be found the graceful B. Gloire de Lorraine, whose parentage is said to be B. socotrana and B. Dregei, a small white-flowered species from South Africa. Few plants have had such a period of popularity, and numerous lectures, essays and articles were published some years ago concerning its culture. It is a pretty shade of pink, free-flowering, easily grown and, with due attention paid to staking and tying, some fine specimens can be secured. The plants are also useful for hanging baskets. Others belonging to this section are Mrs. Leopold de Rothschild, the white Turnford Hall, and Rochfordii.

The most noteworthy group, however, is that derived from the intercrossing of B. socotrana and the tuberous-rooted varieties; and two firms—Messrs. Clibrans of Altrincham, and the late J. Veitch and Sons of Chelsea—are famed for the production of these beautiful plants. The latter firm were the pioneers, and the first variety to be placed on the market, in 1883, was named John Heal. This is still to be found in collections; and others followed, such as Mrs. Heal, Ideala, Elatior, Winter Cheer and Ensign; but the plants I find succeed the best are Fascination (bright orange salmon), Exquisite (blush white), Emita (deep orange), Her Majesty (a charming salmon yellow) and Optima (warm salmon orange), a fine subject under artificial light.

THE ARISTOCRAT OF WINTER-FLOWERING BEGONIAS, B. OPTIMA.

Among winter-flowering begonias, B. Optima occupies a high position, and for free flowering qualities it has few equals. It was raised by Messrs. J. Veitch and Sons, Chelsea, and when first shown by them on November 5th, 1912, it received an award of merit from the Royal Horticultural Society. It is the result of intercrossing B. socotrana and a seedling from B. Pearcei.

The flowers are a good size—a warm salmon orange—and in general habit more free and graceful than many.

With the passing of the house of Veitch it is gratifying to know that Messrs. Clibrans and others stock a large number of these desirable plants, and among the hybrids that hail from Altrincham will be found some splendid double-flowered kinds, such as Scarlet Beauty, Sunrise (bright rosy red), Pink Beauty, and others of equal merit.

These delightful begonias produce a wealth of blooms from October till well into January, when the resting period begins, and continues till the end of March. A temperature of 50° to 55° Fahr. is high enough, and the atmosphere should be rather on the dry side; while careful watering is important.

It ought to be remembered that these plants are almost intermediate between the parents, the base being a compromise between fibrous roots and a tuber, but with some varieties the latter is more pronounced, and in such cases they often lose all the old growths and no harm accrues.

Others, however, must be afforded sufficient moisture to keep the stems, as far as possible, in a plump and rigid condition; if not, the root stock occasionally dies. In April, signs of new life will be apparent, and a little more water can be given. Numerous new shoots will appear at the base, and some of these can be utilised for propagating purposes.

Remove the growths with a heel, and insert them in sandy soil, placing several cuttings around the edge of a 3in. pot and rooting them in a close propagating frame. Pot on as the necessity arises, then they will make useful flowering plants next winter. Later struck cuttings are also valuable, as they will bloom freely in 3in. pots, and therefore are ideal for table decoration. The old plants should be re-potted before growth is far advanced, and the rooting medium consists of fibrous loam two-thirds, and one-third clean sweet leaf-mould, with a liberal sprinkling of sharp sand added. The pots should be well provided with drainage, and the plants carefully watered until the roots are established. At one time I favoured annual re-potting, but now some plants go two and three years without fresh soil, and during the growing period they are fed with soot water and weak liquid manure. The result is

Digitized by Google

satisfactory in every way. Except when at rest, these begonias should be grown in an average temperature of 60°, and, where possible, in a small house where the atmosphere could be kept slightly more moist than in the ordinary greenhouse, and the necessary shade given when the sun is bright.

Overhead spraying ought not to be practised to any great extent, and even then only when the weather is dry and hot.

The chief pests are thrips and rust which is caused by a mite, but these are easily destroyed and prevented by periodical fumigation with XL All.

The cultivation of the Lorraine begonias is well understood, but with these it is advisable to root the cuttings early in the year; while I know several growers who raise their new plants from well matured leaves. Anyone who can grow the Lorraine type fairly well need not fear taking up the other winter-flowering begonias, and, if only a small collection is brought together, the owner will possess a group of plants unequalled for brilliance and floriferousness at a time when flowers, except the chrysanthemum, are at a premium. T. W. BRISCOE.

NOTES OF THE WEEK

TWO ALPINE VIOLAS.

HOW our hybridisers have altered the violas! They have fattened their cheeks and plumped up their foliage till they are about as different from their forefathers as is the prize pig of the show ground from the fleet wild boar. Bedding violas are not to be despised in their proper place, but the rock garden should be reserved for species, particularly the mountain ones and their near relatives. Of alpine violas there are few that can rival V. cenisia. I was lucky enough to come across two of its stations in my wanderings last summer, one was the valley leading to Lac Clair from Mt. Cenis, and the other a valley in the heart of the Cottian Alps, far from the beaten track.

VIOLA CALCARATA, IN ONE OF ITS NATIVE HAUNTS.

A PEER AMONG ALPINES, VIOLA CENISIA.

In the valley of the Cottians where I found our viola for the second time, there were literally acres of it, countless thousands of plants—big ones and little ones, babies that were still cradled between two slices of shale and old straggling plants that had wandered a yard or more from their first home. I would defy the most patient of men to succeed in getting up one of these old stagers whole; they wander and dive and come up again and dive again with their vermicelli runners till one gives it up and puts the stones back and looks for something younger. V. cenisia is essentially a scree plant, always among loose stones with hardly a pinch of soil between them; more peculiar still, it seems not to like any other position, for it never ventures on terra firma, be it only a foot away on to the first tuft of grass and we find our viola change to V. calcarata. I do not say that V. calcarata will not grow in scree. It is characteristically a turf plant, but it takes happily to shale and the photograph here shows it growing in what we would call in nursery language "scree mixture." It looks as if it had acquired a fine tuft of housemaid's brush foliage, but this is only a tuft of grass which it has chosen for its companion.

V. cenisia is a peer, undisputed and unmistakable, while V. calcarata comes rather lower down in the scale. The picture of V. cenisia gives one an idea of the size of stones it grows among.—A. GAVIN JONES.

LACHENALIA NELSONI.

WE had a fine display of Lachenalia Nelsoni at the middle of January last year, and we hope to have the same this January. This handsome hybrid is well known among professional gardeners, but I rather think it is not so among amateurs. Yet it is a choice and charming bulbous plant, very well suited for small glasshouse cultivation and room decoration. It also flowers at a time when most plant lovers welcome anything neat and floriferous if grown in a moderate-sized pot. Its golden yellow flowers, too, are certainly shown off to much better advantage under artificial light. Some gardeners say that they do not get the best results from lachenalias unless the bulbs are potted round about the first of September; but we have grown beautiful and floriferous plants from bulbs potted after the middle of September.

Good bulbs are firm and plump and each about the size of a marble; six, seven or eight of these should be set in a 4in. pot among ordinary potting soil, the tops of the bulbs being kept level with the surface of the soil, and about 1in. of space left between the surface soil and rim of pot. After the pots are watered they should be set in a frame, only supplying them with water when the soil is likely to become dry. As soon as the growths have pushed through, the pots should be transferred to a genial growing atmosphere in one of the glasshouses, and more frequently attended to with the watering pan.

L. Nelsoni produces deep green foliage with faintly dark spots on the upper surfaces and near the basal portion of some of the leaves. When the pots are well furnished with leaves the plants may be intermixed with primulas or other low-growing plants along the front of the staging.—DAVID ARMSTRONG.

THE HARDINESS OF CATMINT.

NEPETA MUSSINI, (Catmint) which yields liberally of its misty blue spikes throughout the summer, is one of our hardiest plants, and, be the winter ever so severe, it generally goes through without loss, provided the old wood, which acts as a shelter to the roots, is left. Sometimes, in order to have the borders neat when trimming up in autumn, one notices that the brown and tangled shoots are cut away; the result of this is that many plants succumb. I have seen examples of this during the present winter. Neatness may be carried to excess, as, after all, the old shoots protect the roots, from which in the spring new growths appear. —W. LINDERS LEA.

BEDDING RANUNCULUS.

THE different types of bedding ranunculus are worthy of more favour than they seem to have, for most people admire their flowers and readily buy them when in season. Bulb catalogues invariably mention them, generally as an after thought, and in no great detail. They are not, however, planted along with the ordinary bulbs, but kept until the end of January or later.

The claw-like tubers often arrive in a dried and disappointing state; steeping overnight in tepid water revives them considerably and hastens initial growth. They are planted with the claws downwards, at a depth of 2ins., and they are certain to grow best in a porous, friable loam or raised bed.

One merit of these flowers is that they are "over" early in summer and the beds can then be utilised for late summer and autumn flowers. The Persian varieties are generally earliest, but the French are best for cutting; the Turban sorts are of an intermediate nature, and equally fine.—H. A.

THE CALIFORNIAN FUCHSIA.

THIS really good shrub should be noted by those wanting something uncommon and beautiful. It is quite hardy in warm gardens, but in others the protection of a wall must be allowed, and under this condition the plant grows splendidly to a height of 6ft. and more, with a dense bushy habit. The flowers, borne in clusters from the axils of the leaves, are deep red in colour with pronounced stamens showing, and open in May. The blossoms are not large, but most freely produced, and, as the above name implies, not unlike small fuchsias in appearance; while the leafage is gooseberry-like. A neat and ornamental shrub is an honest description of this subject, the proper name of which is Ribes speciosum —another synonym being Ribes fuchsioides. Incidentally, the best example of this plant it has been my lot to see is to be found at Albury Park, Guildford, a fine bush indeed, growing there as a wall shrub.—C. TURNER.

PULMONARIAS.

THE lungworts are a somewhat neglected race. The best kinds are seldom seen in the average garden and most people associate their name with those unfortunate,

Digitized by Google

spotted-leaved plants of feeble and indecisive colour. Even so, one generally finds a place in the wilder parts of the garden for these and the almost plain-leaved P. angustifolia (arvernensis or azurea), in blue or white, for they are among the earliest of spring flowers and only ask some shady, neglected corner and the most meagre fare. But there are others, as I have inferred, and among these is the Mawson's Blue of the nurseryman. Whether this is an improved form of angustifolia, or azurea, I do not know (the whole race appears to be in a hopeless state of confusion), but it is a plant well worth a front seat in the best of assemblages. But even this fine variety, or whatever it may be, is excelled by a plant that came here obscurely labelled, P.—Munstead Variety. This one has large, rather narrow unspotted leaves and flowers, about ½in. across, of a rich blue tending to violet.

The only red lungwort I have seen which is really distinct and good is P. rubra. This is not the pinky form often sent out under that name. It is apparently a species, a plant of vigorous growth with plain green leaves some 10ins. long and 4ins. across and bold flowers of a rather bricky red (without any of the offending puce), which colour is maintained from first to last. It is one of the earliest to bloom and often the last to cease.

All the pulmonarias positively delight in frequent transplantation. Every third year is not too often to dig up and divide the clumps and the best season to do this is in autumn or early spring. Nor is any time lost by this process, for no plants are quicker to establish themselves and they will generally show their heartiest appreciation for the attention the following season.—A. T. J.

TWO INTERESTING EARLY-FLOWERING SHRUBS.

SYCOPSIS SINENSIS.

IF this shrub flowered at the height or at the end of summer, it would be only of medium interest. Flowering as it does in early spring, during February or March, it is certainly worthy of notice. Apart from its early-flowering qualities, the plant possesses the great advantage of having fine, evergreen foliage.

Sycopsis sinensis is a member of the Hamamelidaceæ tribe, and can attain a height of 8ft. to 12ft. in our climate. It is a native of Hupeh in China, where Mr. Wilson collected it on several occasions during his explorations. In his book, "Trees and Shrubs Hardy in the British Isles," Mr. Bean is rather hard on it when he says that the flowers are "but of little beauty." These are, perhaps, not striking and a little inconspicuous at first, but as soon as a spell of mild weather sets in the beautiful contrast between the felted reddish brown scales that surround the clusters of flowers, the yellow staminal filaments, the red pollen vessels and the bright green foliage makes itself plainly shown. The period of flowering is a long one, so that, although much rests on the weather, a good display is sure to be obtained every year.

A FLOWERING TWIG OF SYCOPSIS SINENSIS.

Although the plant is often described as monœcious, the specimen that carries the twig here figured is perfectly hermaphroditic, flowers having two long divergent stigmas and eight stamens about half an inch long when fully developed. There is no corolla. The flowers are borne on short pedicelled clusters, seven or eight at a time, surrounded by densely felted bracts of brown colouring. Seeds are rarely, if ever, produced in our climate. The foliage is thick, almost coriaceous, ovate lanceolate, 2ins. or more long and about 1in. wide, dark shining green above, paler beneath, with microscopic adpressed hairs scattered in bundles. The young shoots are conspicuously scaly.

Sycopsis sinensis has proved, so far, quite hardy at the Verrières Arboretum at least, and can be grown successfully in any position out of doors, as long as it is somewhat sheltered from the strongest and coldest winds. As a wall plant it is also much to be recommended, looking cheery and bright throughout the year. Its cultivation is very easy; it will grow vigorously in any ordinary good soil and requires no special care.

STACHYURUS PRÆCOX DRAPED WITH ITS DROOPING CLUSTERS OF CREAMY WHITE FLOWERS IN FEBRUARY.

STACHYURUS PRÆCOX.

A native of Japan and introduced long ago, this pretty shrub will probably never become a common one in gardens, owing to the fact that it is of rather slow growth and difficult propagation; two things nurserymen do not particularly like. Yet it is one of the most fascinating shrubs in existence in early spring, expanding its blooms as soon as the sun begins to be felt in February and March. In the rock garden or choice shrubbery it is a picture in itself when given a favourable position in good soil. It grows at the utmost 4ft. to 5ft., but is usually about 3ft. in height. The position it seems to like best is a warm one with some shade. The flowers, are creamy white, borne twelve to twenty at a time on drooping spikes 3ins. to 4ins. long. These flowers last a long time on the plant and are only injured by the severest of frosts. The foliage appears only later in the season when flowering is over, and the leaves are comparatively large, more or less toothed and of a light green colour. Seeds are occasionally produced in mild seasons, but seedlings are of rather slow growth in their early stages.

Another stachyutus, S. chinensis, is occasionally grown in gardens, but shows little difference as regards decorative value from S. præcox.—C. L.

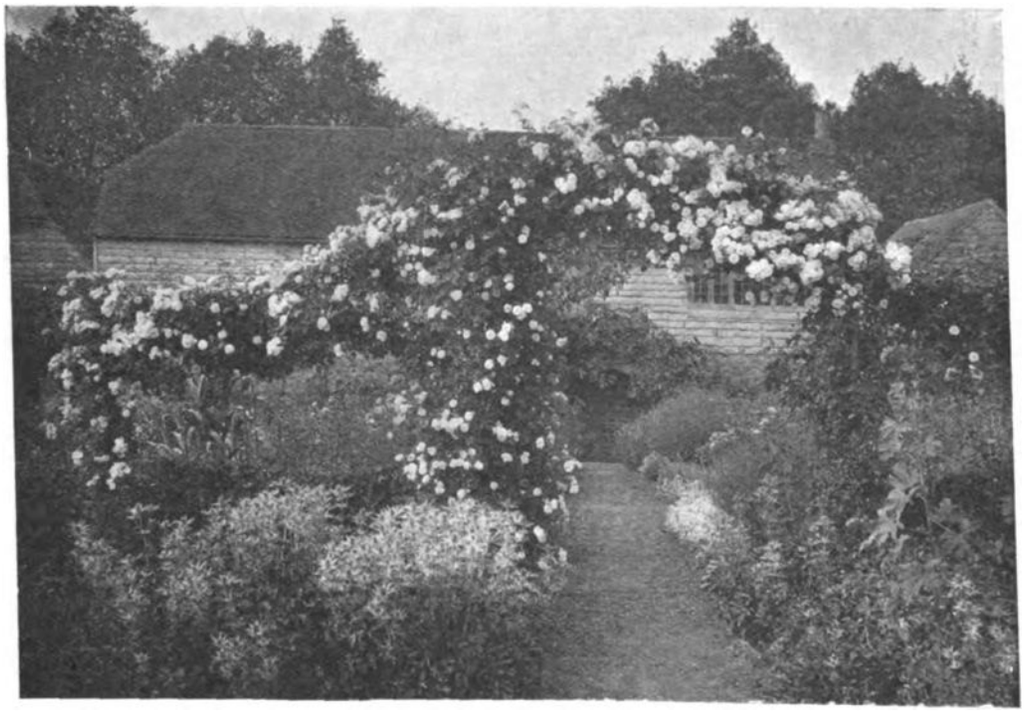
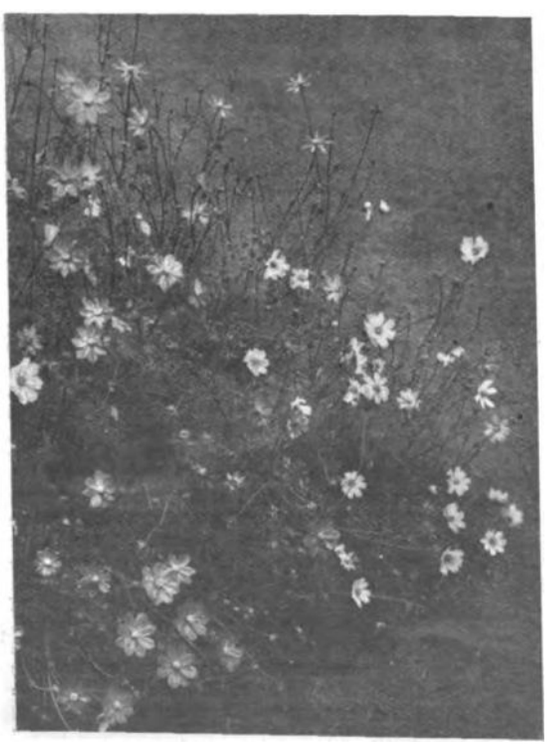
BLUE AND PINK IN THE GARDEN



THE BLUEST OF THE SEA HOLLIES IN COMPANY WITH CLIMBING ROSES.

THE delightful effect of pink May-flowering tulips, such as Clara Butt or Margaret, rising from a mist of blue myosotis is so familiar and so much appreciated that it is a little surprising that the same colour combination is not more often carried out with other plants and on a wider scale. It is one quite easy to manage if certain simple rules are obeyed. In the first place, the blues used, whether light or dark, must be *pure* and this eliminates many plants catalogued as being of that colour, for what may be called nurseryman's blue seems to include everything from slaty purple to skim milk colour. It must be remembered, too, that blue is not a "carrying" colour, that is to say, it is ineffective at even a comparatively short distance, hence it is essential to arrange the plants in larger masses than if they were, say, red or yellow. Yet another point to bear in mind is that, although salmon pink and pure pink are both admissible, they must be kept well apart, while magenta—often misnamed cerise—is absolutely barred.

Of tall blue flowers Anchusa italica Dropmore variety and delphiniums are undoubtedly the best, but the latter must have nothing of the purple, mauve or grey tones seen in many of the more recent introductions. A group of delphiniums of the Persimmon type would make an admirable centre for a large bed filled with the old pink China rose that will bloom untiringly all the summer, edged with the lovely blue Geranium grandiflorum, or for the roses and geranium may be substituted the annuals Lavatera rosea splendens—the improved L. trimestris — and nemophila. But if the garden is frequented by cats, the life of the nemophila will be a short one, as the pussies love to roll on it. Tall pink-flowered plants are not abundant. Pink hollyhocks placed behind and between anchusas and delphiniums would be an ideal arrangement for the back of a border, but they are not to be trusted to come true from seed, and plants raised from



ROSE-FLOWERED COSMEAS ARE MOST EFFECTIVE IN BOLD GROUPINGS.

A CHARMING ASSOCIATION OF BLUE AND PINK ANNUALS.

Digitized by Google

cuttings appear to be particularly subject to that horrible fungoid disease which is the curse of the modern hollyhock. Physostegia speciosa is a good back-row plant, although if the border is a dry one it will not reach its proper height of about 5ft. unless copiously watered in hot weather, and there is, perhaps, just a little too much lavender in the pink of its dainty flowers. Any gaps between the tall perennials may be filled effectively with clumps of sweet peas—Hawlmark Pink is one of the best—and Ipomœa purpurea, which produces as many pink flowers as blue ones, trained on bamboos laced together with string.

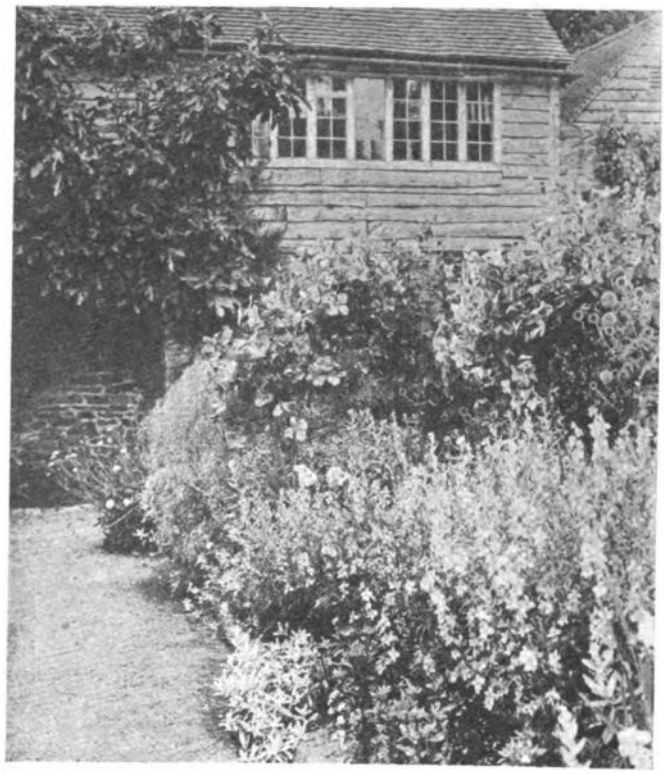
There are plenty of pink phloxes to choose from—Mrs. Milly van Hoboken and Josephine Gerbeaux are two suitable ones—and they may be happily combined with delphiniums of the shorter type and Lupinus polyphyllus. Our native chicory (Cichorium Intybus), which makes a bush about 3ft. high, is unsurpassed for colour, but the beautiful sky blue blossoms are very short-lived and its habit of growth is straggling. Another blue plant of rather untidy habit is Linum narbonense, but its flowers last longer than those of the chicory. L. perenne is a shade darker, but it is not so good as L. narbonense. Then there is the blue thistle, Echinops Ritro, with its glistening metallic blue bells, the ordinary form of which is about 3ft. to 4ft. high, but there is an improved variety which reaches 5ft. As rich in colour, better in shape and immune from the fly which is apt to disfigure the echinops are the eryngiums, of which E. Oliverianum is, perhaps, the bluest. With these sea hollies the tall spikes of the earlier-flowering pink gladioli or of Lilium Krameri—if the soil suits it—will accord delightfully. So will Sidalcea malvæflora rosea, of which there are several satisfactory varieties, although some are a little too near the forbidden magenta. Papaver orientale Mrs. Perry, the only poppy of the kind that has any true claim to be called pink, is distinctly salmon in shade, but it, too, goes well with eryngiums if none of the purer pinks is put near it. Chinese peonies must, of course, be included among the most desirable of pink plants, nor should Veronica spicata, blue and pink, be forgotten.

Two pretty plants for the front of the border are Anchusa myosotidiflora and Omphalodes cappadocica. Both are of a rather pale shade of blue, grow about 1ft. high, flower in late spring and early summer, and prefer slight shade to full sun. I may add that in my garden the anchusa suffers badly from the attacks of slugs, which leave the omphalodes almost untouched.

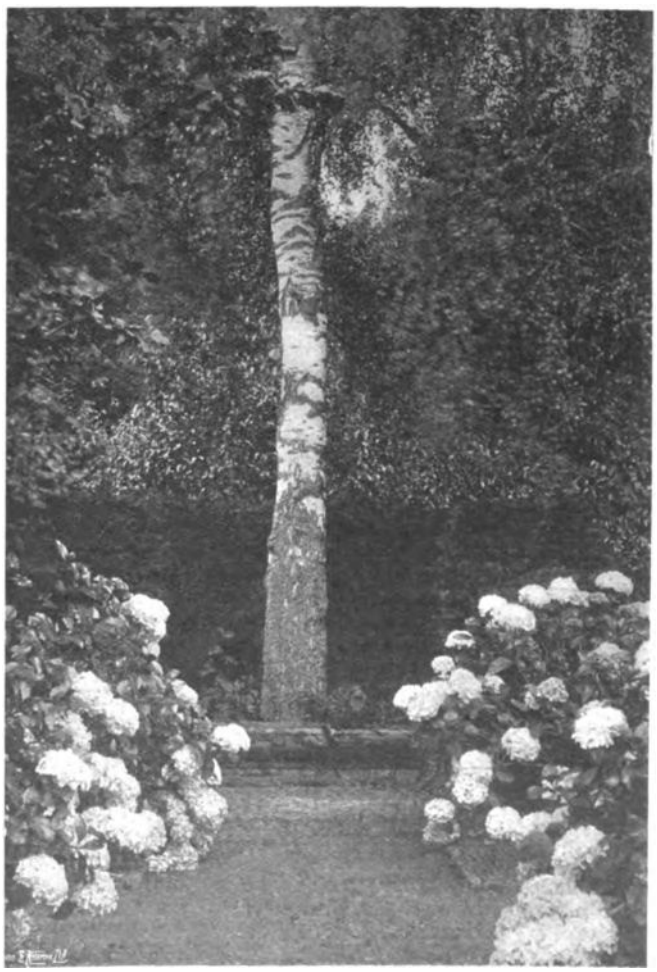
The flowers of Commelina cœlestis are of a very rich blue, but it is not hardy everywhere. For the sake of its fine colour, however, it is worth trying if the border is warm and sheltered. It should be planted in good-sized patches with carnations or Allwoodii pinks between. Mertensia pulmonarioides has equally rich-hued blossoms, but it requires a moist and preferably a peaty soil.

The majority of campanulas are too purple to harmonise well with pink, but C. rotundifolius major is an exception. This graceful plant looks particularly charming if combined with Potentilla Miss Willmott, so that the slender stems of the blue bellflower are surrounded by and rise through the graceful sprays of rose-pink flowers. Of quite low-growing blue plants the best are Lithospermum prostratum Heavenly Blue and that which we used to know as Plumbago Larpentæ, but is now, poor thing, burdened with the terrific name of Cerastostigma plumbaginoides. The colour of both these is desirable, and they may be successfully combined with pink helianthemum, Phlox subulata and some of the dianthus.

There are several annuals in addition to those already mentioned which may find a place in a blue and pink bed or border. Cosmos is a particularly valuable one. It is to be had in a good shade of pink and if planted out from pots in front of and close to delphiniums, it will come into bloom after the beauty of the latter is over, and its feathery foliage will hide the decrepit stems. Then silene is useful and pretty as an edging, and China asters can now be obtained of a pink that has no taint of magenta. The same may be said of antirrhinums (which in these days are usually grown as annuals, although nominally perennials) and of ten-week stocks. A pretty annual climber growing about 4ft. high is the chickling vetch (Lathyrus sativus). Its delicate little flowers are of the most perfect turquoise blue, but they have the drawback of "going off" a dingy grey. Phacelia campanularia is a pretty blue edging annual, but is not very long-lived.



A CORNER OF THE BLUE GARDEN.



THE BEAUTY OF HYDRANGEAS WHEN GROWN IN TUBS.

Digitized by Google

A broad turf path between blue and pink borders would make a pleasing approach to a little semi-circular rose garden, if possible slightly sunk and reached by shallow steps under a rose-covered arch. In the garden there should be roses of every shade between faint blush pink and deep crimson, but none that is white or yellow. These—standards, half-standards and bushes backed with climbers on poles or a treillage—should fill a wide border round the little garden, which may be turfed and have a weeping standard of such a rose as Lady Godiva or even the hackneyed but useful Dorothy Perkins in the middle, or, if water is available, there may be a pool or tank here edged with Iris Kæmpferi and Myosotis palustris in its improved and larger form. And, to be absolutely consistent in our colour scheme, we may grow a pink nymphæa in the pool itself! Under-planting the roses in the border is not necessary—it is questionable whether it is ever really desirable—but the latter may be edged with a wide band of a blue annual such as Phacelia campanularia or nemophila, or with a mixed selection of low-growing blue plants. There is, unfortunately, no pure blue viola—which would be ideal in such a position—the varieties so called having lavender flowers merely tinged with blue.

A pretty finishing touch to the little garden might be given by flanking the entrance arch with tubs of agapanthus or, as an alternative, of "well blued" hydrangeas.

R. E. HEAD.

THE PROPAGATION OF TREES AND SHRUBS

THE propagation of trees and shrubs is one branch of gardening which has been practised in comparatively few private gardens until within the last ten or fifteen years. The introduction of large numbers of new trees and shrubs from China and elsewhere during recent years—the great majority by means of seeds—has greatly increased the interest in this department of horticulture. The increase in the cost of everything in connection with greenhouse or indoor gardening has also induced some—one may even write many—owners of gardens to turn their attention to outdoor gardening, a less expensive department, both in the materials required and the amount of labour necessary for its adequate upkeep.

Among the half-dozen or more methods of multiplying stocks of trees and shrubs, seed, with a few exceptions, provide the easiest and simplest means of increase. The outstanding exception is that of hybrids and improved varieties, variations or sports which seldom reproduce true from seed, though as an offset against this we have the possible chance of a seedling from a hybrid being an improvement or fresh break on the seed-bearing parent.

One point in the raising of seedlings is that they are generally healthy and vigorous, with an abundance of roots, which is a great asset to begin with. Other than the collecting of seeds in one's own garden, and the exchange of seeds with friends, the question of how to procure seeds of trees and shrubs presents some difficulties. The number of kinds listed by a few British dealers does not extend much beyond the comparatively few deciduous forest trees and conifers sold in quantity mostly for forestry planting. Some of the lists of seeds compiled by botanic gardens for exchange contain a fair number of trees and shrubs; but they do not cate for an extensive retail distribution of seeds.

In addition, we are confronted with a large number of exotic trees and shrubs, the former in particular, which, owing to their age or because our climatic conditions are not favourable, do not ripen their seeds in our gardens. Enthusiasts cultivating trees and shrubs extensively, to make it worth while, find ways and means of obtaining seeds from the Continent and direct from dealers in their native countries—Japan, China, the United States, and other countries,

A cool greenhouse, pit or cold frame is desirable when raising small quantities of seeds. In fact, when large numbers of certain kinds are required it is often worth while preparing beds and sowing the seeds in cold frames, or sowing on a border outside and covering with movable frames. In addition to protection from birds and mice, the heat derived under the glass should hasten germination and increase early growth.

There are several important points to be considered when contemplating the sowing of tree and shrub seeds. The best time to sow—or, at least, the time when they may be sown—varies considerably with the different genera. For the larger number which germinate under ordinary conditions, the spiræas, hypericums, philadelphuses, buddleias, etc., a good time for sowing is during February, when the days begin to lengthen and the sun heat gradually increases. The soft fleshy or oily seeds, which include magnolia, quercus, æsculus, castanea, juglans, corylus and fagus, soon lose their vitality if stored under dry conditions. It is advisable to sow these as soon as ripe, or they must be stored in sand or fibre with sufficient dampness to prevent shrivelling. Another group of seeds with a hard or bony outer covering—the berberis, rosa, cotoneaster, prunus, pyrus and cratægus are examples—are very uncertain and irregular in germinating if stored for any considerable time to allow the bony exterior to become very hard. One or two years, occasionally more, may elapse from the time of sowing to germination. Experience suggests sowing such seeds in a slightly heated greenhouse when gathered, removing them from the fleshy fruits, which should be done about late autumn. One record will serve as an example. Seeds of a rose were taken from the fruit when gathered in October and sown within a week. In from a month to six weeks there was a small pot full of healthy seedlings. This, I am quite prepared to admit, was exceptional, but it serves to illustrate my point that such seeds should be sown at once rather than stored in packets under dry conditions until sown in spring. A practice in nurseries when dealing with large quantities of such fruits as holly and thorn is to mix them with sand, stirring over occasionally for six months, or even a year, until the fleshy portion has rotted, before sowing the seeds. A method we adopt with any of these hard, bony seeds which are sluggish in germination after a reasonable period in a heated greenhouse, is to plunge the pots to the rims outside in autumn where they are exposed to changes of temperature and moisture—frost, rain, snow and drying winds. There are usually a good many vacancies before spring where pots of seeds have germinated and been moved under glass.

In March or early April the laggards are returned to the heated greenhouse, where generally the sudden change from outdoor to warm indoor conditions induces still more to germinate.

In dealing with small, dust-like seeds—the rhododendrons and spiræas, for example—it is not desirable to sow these until early spring, as they invariably germinate in a short time. Young seedlings of this type are fragile, requiring favourable conditions, which are easier to supply at that season than during November and December. Roses, thorns, cratægus, etc., are more sturdy if sowing is carried out as soon as the seeds are ripe, and germination takes place by November.

The questions of clean pots, porous sandy soil and ample drainage are similar, whether greenhouse seeds or tree and shrubs seeds are sown. The depth to cover the seeds is important. A useful and safe rule to follow is to cover the seeds with about their own depth of fine sandy soil. This means that the finest seeds need scarcely any covering. Rhododendrons, for example, should have only a light dusting of fine silver sand, using, of course, a lime-free soil on which to sow the seeds.

Avoid sowing the seeds too thickly. It is a waste of seed and may result in drawn-up, weakly seedlings, or losses through close contact and damping-off.

Protect the rhododendron and other fine seeds with sheets of glass until germination begins, and cover all the seeds with sheets of paper to conserve the moisture in the soil and obviate frequent watering.

When germination begins and the papers are removed, pay special attention to atmospheric moisture and the condition of the compost. A dry soil and dry atmosphere may soon cause untold losses among seedlings, as also may the excessively moist condition of the compost. A. O.

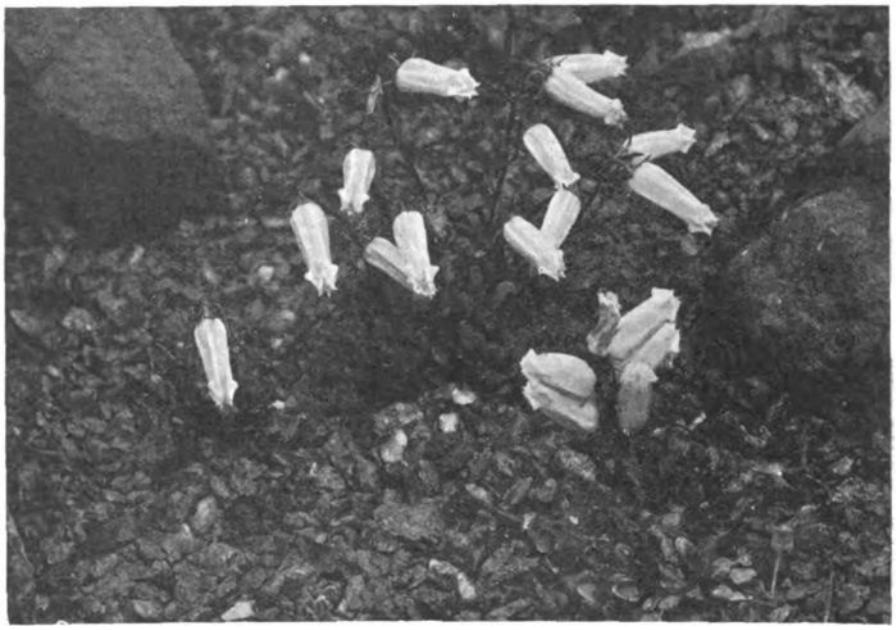
CAMPANULAS FOR THE ROCK GARDEN

CAMPANULAS, on the whole, are an extremely satisfactory and pleasing family, and are almost indispensable where rock gardening is a feature. They are usually easy to cultivate, but some odd species require a little more attention and patience to grow them well; but in certain instances some lovely individuals have unfairly been given a bad reputation. Take the charming C. Zoysii as an example: 90 per cent. of rock garden owners consider it is too difficult to grow. But for what reason? I, personally, do not agree with them, although I must admit that it is one of the favourite "dishes" of the slug, and, because it is devoured time after time by this pest, I imagine that it has thereby earned its unworthy reputation. If sufficient precaution be taken to guard against such pests, I have not the slightest doubt that C. Zoysii would thrive and become a perfect little treasure. From June to August the campanulas are in flower and some varieties continue still later, a feature which makes them particularly valuable, as by July the majority of rock garden plants are almost at the end of their season of beauty. The campanulas need an open sunny position, and a good addition of sharp sand and grit to the soil. Some of the species described below make choice items for pan culture in the alpine house or any airy, cold house; and in cases where they are particularly liable to attack by slugs, it is a simple matter to make their destruction impossible, by standing the specimen pan on an island in a saucer of strong salt water.

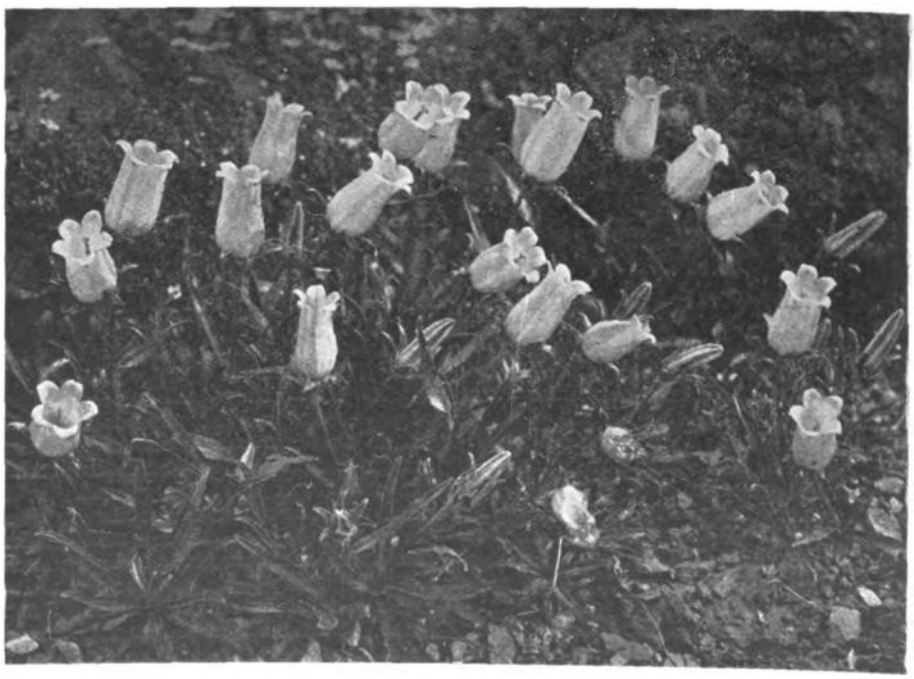
CAMPANULA ARVATICA (ACUTANGULA), is a delightful scree plant, where it will run about freely among the loose grit and stones and become a mass of splendour when its myriads of flowers appear on their tiny slender 2in. stems at midsummer. The tiny emerald green foliage hugs the surface of the soil, hardly rising half an inch high, and the rich violet flowers sit with their wide open stars erect and looking to the skies. It is a lime-loving species. In winter it remains dormant and unseen, save for its dead, ripened growth of the preceding season.

CAMPANULA EXCISA is a native of various European Alps, occurring, I believe, on granite or, at least, non-lime formations, but I do not think that a little lime will be too detrimental towards its culture, as, on one occasion, I imported a certain androsace which I grew in limestone chips, leaf-mould and sand. To my surprise, the following spring the specimen was densely surrounded by small, wiry growths of some campanula. From a point of view of curiosity, I allowed it to remain, to see what it really was, although it seemed as if it might strangle the androsace at any time. However, the intruder proved itself to be C. excisa, and it caused no little trouble before the last remains could be cleared away. This is my reason for believing that C. excisa is not a true lime-hater, but at the same time, as a most desirable compost, I would suggest a very sandy leaf-mould. It runs about and sends up fine wiry stems clothed with small lanceolate leaves, finely notched, topped by nodding deep blue bells, each being borne singly. They are long and tubular in shape, and deeply and curiously cut, making five distinct points. At the base of each lobe there appears to be a hole punched, but on close examination these are found to be an extraordinary division which forms in the lobes. This is a pleasant characteristic of the species, and one by which it may always be recognised.

CAMPANULA WALDSTEINIANA is a most distinct species for a well drained, gritty soil and a sunny aspect. Being fond of lime, abundant chippings of limestone should be included in the compost. Tufts of dark green growth are formed of small oval leaves and short sturdy stems, and in summer it is a perfect dense mass of flowers, starry cups open to the skies, of a violet hue, fading to a paler shade in the centre. Its height may be 3ins. to 6ins., for old and well established tufts increase in size year by year. No underground runners are sent out.



THE MINUTE C. ZOYSII, ONE OF THE MOST CHARMING OF THE FAMILY.



C. ALLIONII. WITH ITS CLOSE-GROWING ROSETTES OF LEAVES AND LARGE BELL FLOWERS.

Digitized by Google

CAMPANULA TOMMASINIANA is only occasionally met with in cultivation, although it is a most desirable species. This is due to the fact that its native habitats are few and local. It is of good habit, forming a neat tuft of fine, wiry growth in summer, with long elliptical leaves edged with fine teeth. Six inches is the average height of well established plants, and year by year the tuft increases in size. The slender stems carry pendent, dangling, tubular bells, extremely pretty and fairy-like, of a pale blue, distinctly flushed with a lilac shade. A choice sunny corner in the rock garden, in light, sandy, open soil, should be chosen for this campanula.

CAMPANULA ALLIONII comes from numerous European stations, where it is very plentiful on lime-free formations, which no doubt gives the reason, in theory, that it is a lime-hater but actually the plant will thrive and flourish in cultivation in limestone scree or moraine. Rosettes of long, strap-shaped leaves, covered with short sturdy hairs, sit perfectly flat on the soil's surface, and flower stems not more than 2ins. high ascend to carry the enormous blossoms, which resemble, in size and shape, the Canterbury bell. But in this case they are carried singly and at right angles to their stout stems. The flowers vary in colour from shades of blue to deep purple: as also does the foliage, from green to silver. A position near the ground where its roots will be cooler in summer is most suitable. A deep compost, of a very open, gritty character is necessary, so that the roots may run about freely underground and produce the numerous white shoots which eventually find their way to the surface and make new rosettes. The roots are not fine and threadlike, as they are in many other cases, but are stout and fleshy, with a limited number of small fibres.

CAMPANULA ZOYSII undoubtedly ranks among the choicest species, dainty and unique in appearance and, generally speaking, is an outstanding little treasure, of neat and compact habit. It forms short tufts of densely furnished stems, of bright glossy green leaves, which are small and oval, and it rarely, if ever, exceeds 3ins. in height. The flowers are most fascinating and attractive, and take a peculiar form in quite original style. They are tubular in shape and about half an inch in length with a wider base. Instead of an open bell, the mouth is contracted and closed, which gives a curious star-fish appearance from a direct front view. It loves a deep limestone crevice, or a position where it can be firmly wedged between rocks, but, as previously mentioned, it is not a difficult plant to grow and any good scree mixture will suit. An occasional dusting with Sanitas Powder, or if the plant is encircled with a barrier of powdered alum or a collar of zinc, safeguards it from its particular enemy, the slug. For the alpine house it is a very desirable subject on account of being more safely protected by standing the specimen pan on a raised island in a saucer of salt water. It flowers abundantly in July and August, and is found in rock crevices and lime formations in the eastern Alps.

CAMPANULA CENISIA.—From the lime-free screes and moraines of the high Alps, perhaps chiefly from the vicinity of Mont Cenis, from where it takes its name, this delightful subject comes to us. It is a subject suitable only for scree treatment in cultivation, and, even so, it is not an easy matter to overcome the difficulties it is likely to present. Where it is made happy, however, it will run freely among the stones and produce its delicate light green rosettes of small round leaves. Its Cambridge blue flowers form shallow bells with wide mouths, exquisite and dainty. A recommended mixture as a growing medium may be made up of three parts granite chippings and one part leaf-mould and sand.

CAMPANULA MORETTIANA is, again, another item for the enthusiast and specialist, as it is extremely beautiful and rare. It is to be found in the Dolomites haunting high limestone formations in more or less inaccessible positions. A tight, well drained, deep crevice with abundant lime should meet its requirements in cultivation, or limestone scree treatment may suffice. Its foliage is a dark grey-green colour, and its small divers-shaped leaves form a neat and compact tuft, from which its large violet bells ascend, borne singly on 2in. stems.

CAMPANULA RAINERI is one of the most charming and satisfactory subjects for the rock garden, where it will thrive in almost any sunny, well drained pocket or crevice, making compact clumps of dwarf greyish tufts, capable of a brilliant display of large open bells of a bright blue colour. It is particularly fond of limestone, and is partial to a deep crevice, though this is not essential. It is important to place it in a position where it is not likely to be troubled by slugs.

CAMPANULA SAXIFRAGA is a rare and beautiful species from the Caucasus, with handsome silvery grey rosettes of long narrow leaves, probably more pronounced at the base than the centre. The leaves appear shorter and broader in the centre. Numerous large dark blue bells of high quality are borne during the summer. It is an easy doer in gritty compost in a sunny position. Almost identical with this species is C. tridentata, requiring exactly the same treatment.

F. BARKER.

NOVELTIES IN SWEET PEAS

(*Continued from page 26.*)

DIANA (Ireland and Hitchcock).—I do not recollect having seen this pea, so the raisers' description must suffice. "A very unique variety. The whole flower is pink on a white ground, while every vein is a clear rose." Certainly uncommon.

HEAVENLY BLUE (Waller-Franklin Seed Company).—"Soft, pure delphinium blue with no trace of violet." Another American mid-blue to dispute pride of place with Mrs. Tom Jones, a true stock of which I still consider to be at least equal to any other mid-blue in existence, although I am fully aware there are many bad stocks of it in commerce. The raisers tell us Heavenly Blue is a "marked improvement," and while bearing in mind the different way in which some peas behave in California, I have no hesitation in commending this novelty as well worthy of a trial.

JOY (F. C. Woodcock).—The fact that Joy is a pale rose-pink form of Cecily, with all the good qualities of the latter, is no light recommendation. I should imagine it to be between the colours of Hebe and Valentine. Vigorous and long stemmed.

2LO (E. W. King and Co.).—2LO is a very decided advance in colour. Its raisers term it a scarlet, but dense shining orange-scarlet or deep brilliant scarlet-cerise will fit it equally well. It is shades deeper than Grenadier or Pimpernel, a solid, satisfying and glaring self tone that arrests the eye immediately. Camp Fire, a 1925 novelty, is its nearest rival as regards colour alone, but the older pea is not so deep or rich and its blooms are rather on the small side. As exhibited 2LO, seemed hardly as large flowered as Grenadier, but even if this is so it is undoubtedly a really good pea, and most certainly one of the best 1926 novelties, and all who grow sweet peas will not regret including it in their selections. I tender the same advice to exhibitors as in one or two other instances, namely, to give 2LO liberal treatment and to restrict it to one stem.

LESLIE RUNDLE (E. W. King and Co.).—A black-seeded cream with a tendency to give duplex standards. Its raisers tell us "its chief characteristic is the length of stem it maintains, both growing naturally and for exhibition, a claim which cannot be urged for any other cream." Certainly a strong point.

MAGNET (Thomas Cullen and Sons).—I should describe this as a cream ground Pink Perfection. The colouring is very rich, and at the Scottish National Sweet Pea Society's trials it was awarded the gold medal. Its raisers say "Magnet will, we predict, take premier place for form, size, richness of colour and refinement, the pink tone being brighter than in any other cream-pink." It has two exceptionally strong rivals already in commerce of somewhat similar shading, W. J. Unwin and Miss California, both superb peas. If Magnet can hold its own with them for size and shape of bloom, vigour and length of stem, it is well nigh impossible to predict which of the trio will eventually be generally considered the best.

MARY PICKFORD (C. C. Morse and Co.).—I entirely agree with its raisers'

Digitized by Google

statement "One of the best Spencer varieties yet introduced." Like the dainty lady after whom it is named, this novelty is very charming. One would not be far off the mark in describing Mary Pickford (the pea, I mean) as a light Miss California, yet this does not seem to convey quite enough to indicate its attractiveness. A beautiful light cream-pink with the faintest suffusion of salmon, it is not in the least insipid and will be found excellent for all decorative purposes. The growth is vigorous and it is large bloomed and long stemmed. Mary Pickford will surely maintain the reputation Messrs. Morse have won with their previous excellent introductions Youth and Miss California.

MAUVE PRINCE (A. Ireland and Hitchcock).—"The standard is a rosy-mauve and the wings pure mauve." The raisers also add "We have every confidence that it will become exceedingly popular."

MERMAID (Thomas Cullen and Sons).—It will be remembered that Messrs. Cullen were the raisers of Powerscourt, which can be accurately termed the most popular present-day lavender. Mermaid is a seedling from Powerscourt, and its raisers consider it superior to the latter. From what I have seen of Mermaid, its colour is something like Lord Lascelles or Cynthia, but its lavender tone is richer and the blooms have a decided blue sheen. Although I do not know for certain, I believe it was No. 56 at the N.S.P.S. 1925 trials; if so, I was very impressed with its beautiful colouring. Undoubtedly one of the best 1926 novelties and well worth a trial.

MISS PHILADELPHIA (W. Atlee Burpee and Co.).—Claimed to be an entirely new shade of pink, "a pleasing warm shade of rosolane pink, lightly suffused with pale amber and salmon." Almost a self colour. It is vigorous, large bloomed and long stemmed.

MRS. HORACE WRIGHT (W. J. Unwin).—I can fully endorse the raiser's description "It is as large flowered as W. J. Unwin, of perfect form and placement, with no faults as far as we are aware. The delightful colouring is a warm and rich shade of rosy-pink with just a suspicion of cerise, flushed on a pure white ground. Exceedingly vigorous and ideal for any purpose." I shall be surprised if this pea does not prove to be the best white ground flush.

ORION (A. Ireland and Hitchcock).—"A pale cream, pink suffused with salmon." The raisers give the following opinion: "Although we have many cream-pinks, we have not one that can compare with this variety for perfect flowers." As far as I am aware, I have not had the pleasure of seeing Orion, so cannot give my personal impressions.

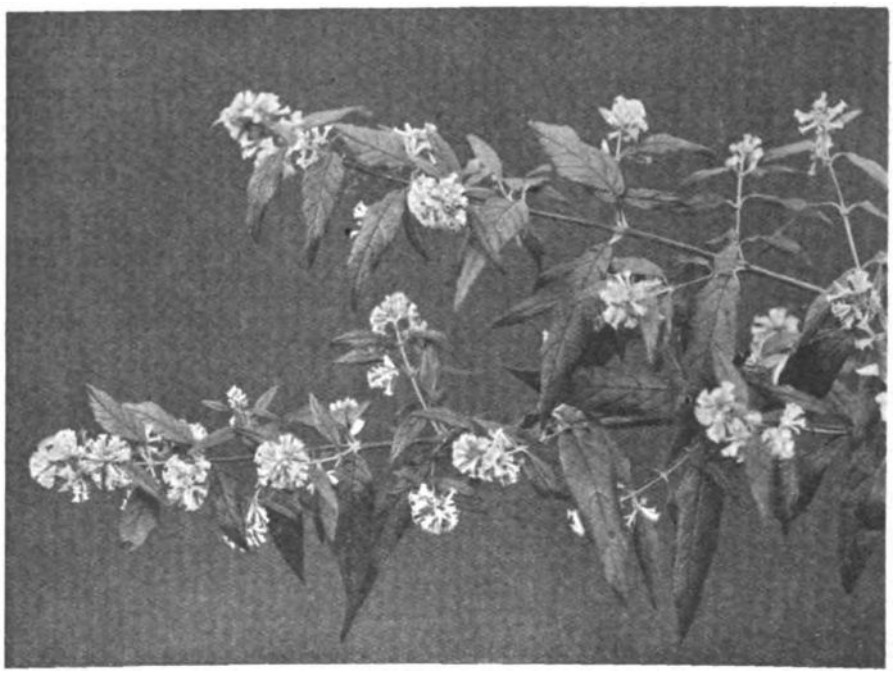
PEGGY (R. Bolton and Son).—I found, on comparing Charming, Coralline and Peggy, that the last named was the brightest of the three, but I have not yet had the opportunity of comparing it with the other three 1926 deep cerise novelties Centaur, Coral Glow and Ryburgh Cerise. Centaur and Coral Glow I also know to be deeper than the older pair, so the cerise colour class is likely to provide us with more than the usual interest next summer. Strangely enough, the deep cerise colour section in the past has had few representatives, now they are coming in with a rush. The blooms of Peggy as exhibited were faultless, and I think there is no question as regards its size. Should it prove to be as vigorous and long stemmed as Charming, I expect it to head its colour section. C. H. A. S.

(To be continued.)

CORRESPONDENCE

FLOWERS BLOOMING IN THE OPEN AT CHRISTMAS.

SIR,—I send you herewith a list of flowers in bloom to-day in Mr. G. W. W. Blathwayt's garden and in my own at West Porlock, Somerset. The previous Christmas we were able to record over 200 varieties, but, naturally, the recent severe frosts have considerably reduced the number at present, and have also affected their quality. A few plants have been given the shelter of a hurdle, but the majority are quite unprotected. The leptospermums have been in full flower since early in November and were untouched by 8 degrees of frost. Abelia floribunda; Abutilon megapotamicum; A. Canary Bird and red var.; Acacia falcata; A. longifolia; Arbutus Unedo; Araujia sericifera; Arabis albida; Aubrietia vars.; Achillea Lewisii; Antirrhinum majus; Agathæa cœlestis; Berberis japonica; B. verruculosa; Bomarea multiflora; Bowkeria Gerrardiana; Buddleia auriculata; Brachysema Drummondii; Calceolaria alba; C. integrifolia; Cassia corymbosa; Cassinia fulvida; Campanula persicifolia; C. Portenschlagiana; Callistemon speciosus; Clianthus puniceus albus; Clematis cirrhosa; citrus (citron); Coronilla glauca pygmæa; C. valentina; Crocus Imperati; Ceanothus azureus var.; C. Veitchianus; Chrysanthemum (many vars.); C. marginatum; C. maximum; C. frutescens; Cheiranthus Newark Park; C. Harpur Crewe; C. linifolius; Cobæa scandens; Cuphea ignea; Cyclamen Coum; Cytisus monspessulanus; C. racemosus; Chorizema cordatum; Correa Harrisii; C. pulchella; C. magnifica; Cydonia Maulei; Daphne Philippii; Dianthus caryophyllus vars.; D. plumarius vars.; Diosma ericoides; Diplacus glutinosus Erica codonodes; E. Veitchii; E. gracilis (pink and white); E. stricta; E. vagans; Epacris sp. (red); Erodium hymenoides; Erigeron mucronatus; Eupatorium Weinmannianum; Escallonia montevidiensis; E. langleyensis; Freesia refracta (seedlings); Fuchsia Cottinghamii; F. excorticata; F. reflexa; Galanthus cilicicus; Gazania hybrida; Gentiana acaulis; G. sino-ornata; Grevillea rosmarinifolia; Geum montanum; G. Lady Stratheden; Hamamelis mollis; Helianthemum var.; Helichrysum bellidioides; Helleborus corsicus; H. niger; Hydrangea hortensis vars.; Iberis sempervirens; Ionopsidium acaule; Iris unguicularis; I. u. cretensis; I. u. lazica; Jasminum nudiflorum; Kennedya Comptoniana; Leonitis Leonurus; Lavendula dentata; Leptospermum scoparium; L. s. Nichollsii; Linaria alpina; Lithospermum prostratum; L. rosmarinifolium; Lapageria rosea; Lonicera fragrantissima; L. Standishii; L. sempervirens; Matthiola (stock); Malvastrum phœniceum; Malva Olbia; Menziesia polifolia; Mesembryanthemum blandum; M. Ecklonis; M. atro-violaceum; M. compactum; Medicago arborea; Nicotiana affinis; Olearia ramulosa; Omphalodes cappadocica; Pentstemon (garden vars.); P. tubiflorus; Pelargonium Ivy-leaf; P. Zonal; Pittosporum Tobira; Primula cashmiriana; P. malacoides; P. obconica; P. veris vars.; P. vulgaris vars.; P. Juliæ hybrids; Polygala Dalmaisiana; Prostanthera rotundifolia; Pieris floribunda; Passiflora cœrulea; Phlox Arendsii; Rosmarinus officinalis; R. prostratus; Reseda odorata; roses (teas, h.t.'s, Wichuraianas); Rubus Bambusarum; Rehmannia angulata; Rhododendron lutescens;



THE GRACEFUL FLOWER CLUSTERS OF BUDDLEIA AURICULATA.

Digitized by Google

Salvia rutilans; S. fulgens; Schizostylis coccinea and var.; Sollya heterophylla; S. Drummondii; Solanum jasminoides; Spartium junceum; Senecio Grayii; S. lanatus; Spiræa prunifolia; S. Thunbergii; Tacsonia quitensis; Triteleia uniflora; Viburnum fragrans; V. Tinus; Veronica catarractæ; V. speciosa; V. hybrids (numerous); V. spicata; Vinca difformis; V. major; Viola odorata (single and double); V. gracilis Lady Crisp; V. tricolor..—N. G. HADDEN.

HOLLY AND MANURE.

SIR,—I have a Silver Queen Holly which has been for the best part of a century growing in full sun among other shrubs, but never making much growth, and also being a good deal nipped for Christmas decorations, and it has also been depleted by hostile hands, with the result that the dwarf plant never progressed. Some two years ago I had it heavily top-dressed with rich manure. The result is that a strong leading growth now about 10ft. high and as straight as a fishing-rod has appeared.—J. HILL POE, *Riverston, Nenagh.*

PLANTING.

SIR,—The Editorial comment in the first issue of THE GARDEN for 1926, on autumn *versus* spring planting, was sound commonsense, and it gives food for thought to all who have planting to do. In February, 1874, I began to read THE GARDEN, and have been a weekly reader ever since. During this long period of time I have had every kind of experience in the planting and transplanting of every conceivable phase of the work. Therefore I endorse plain speaking and calling a spade a spade. Nurserymen are often blamed for many trees and shrubs going wrong after planting; in some cases it may be so, but I venture to assert that more go wrong through the planter and the planting. So, whether it be autumn or spring, if there is indifference in any of the work to be done, indifferent results will follow. To all who value helpful hints I suggest the following as useful factors to practise. Let all preparatory work of digging or trenching the ground be of the best possible order, as it ensures a better rooting medium. In taking out holes for whatever kind of planting is being done, let the bottom be as wide as the top, so that the spread of the roots is not cramped but well set out on a flat bottom. This gives a firmer hold in the space allotted, and is a greater safeguard against the wind loosening them so soon after planting. On receiving all packages from a nursery, closely examine all roots, so that any that are damaged may be cut back with the sharpest of knives or shears—a clean angle cut just beyond the damage; when this is done the cut will callus round the edge and new fibrous roots will grow and be valuable support. Never plant anything with dry, parched roots; where this condition occurs, get a tub of water and soak all roots overnight until thoroughly saturated. Where there are balls of roots and earth bound together, it is most important to see that they are not planted dry, or disappointment is sure. Never begin to tramp the soil or earth on or about the roots until there is enough placed about and over them to prevent injury, and to make sure that the soil gets well among and round about the roots, move the plants to and fro while filling in, and in this way you make more sure there is no vacuum or empty space about the roots, because where this is so it is an evil of bad planting. The depth to plant must always be a matter for the planter to decide, according to the subject being planted; but, above all, see that everything is firmly finished by a reasonable tramping and all foot trampings forked out, so that everything is left decent and in order.

Staking is a matter to be decided upon at the discretion of the planter. Personally, I give my opinion that all planting done from now on to the end of March, under all conditions proper to the needs of the subjects to be planted, is the best possible time.—V. H. LUCAS, *Hurworth-on-Tees.*

ERITRICHIUM NANUM.

SIR,—I have been much interested in the correspondence in THE GARDEN about Eritrichium nanum, and would like to have the opportunity of saying how heartily I agree with Mr. Clarence Elliott's and Mr. F. Barker's letters and to show that one person, at any rate, appreciated the gem of the Alps entirely upon its own merits. The first time I was fortunate enough to find this lovely plant was one July day before the war, when I was coming over the Col d'Hérens from Arolla to Zermatt and stopped to rest upon the Stoekge at an altitude of over 9,500ft. Here I suddenly came upon several large patches with their wonderful pure azure blue flowers, the purest blue I had ever set eyes on, gleaming amid the glacier snows and leaving me absolutely speechless before the most perfect rock gem conceivable. Dare I admit, ardent lover of all flowers as I am, that at that time I had never even heard the magical name of Eritrichium nanum, and dare I further admit that, with infinite pains and trouble, I then and there proceeded to grub up a plant which, in my crass ignorance, I sent home to Scotland, had planted in the open and, to my infinite disappointment, naturally lost? Surely this is another testimony to the beauty of the flower entirely upon its own merits. Since then I have found it several times in the neighbourhood of Zermatt, and always with the same marvellous pure blue flowers without any of the traces of pink complained of by a previous correspondent.—ETHEL S. HOWARTH.

CHRYSANTHEMUMS IN CANADA.

SIR,—The illustration of chrysanthemums in THE GARDEN for December 26th, 1925, page 730, growing at the Experimental Farm, Ottawa, was very interesting to me, as it was my great privilege to see them there in September last.

Mr. McKee, the Dominion greenhouse specialist, who stands with the plants, informed me that chrysanthemums in Canada are grown entirely under glass because of the climatic conditions there.

He showed me hundreds of seedlings from which he was hoping even to improve on such excellent varieties as Lady Byng and J. R. Booth.

Chrysanthemums are more difficult to grow in Canada than in England, and the photograph reflects the greatest credit on Mr. McKee's skill as a cultivator of these plants.—THOMAS MOORE.

CHRYSANTHEMUM SOURCE D'OR.

SIR,—I was delighted with "Claremont's" reference to this really grand old decorative variety (page 10, issue January 2nd). I too, well remember its introduction and that of the tall-growing Mme. C. Audignier, which I used to grow 12ft. high along with another tall sort, Belle Paule, 13ft. to 15ft. I have stood on a high wall to attend to the tying and disbudding of the shoots. Truly, there were giants in those old days as regards height, but their flowers were refined. But to return to Source d'Or: I, too, grow it and its equally good yellow sport, Lizzie Adcock. If disbudded on their terminal shoots the buds develop into ideal blooms as regards size and deep colour. I regard the two as ideal late October and early November varieties in every way. Usually I plant out and lift about three hundred plants; the plants are good for this, and fill some cleared tomato borders under glass.—GEO. GARNER.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS

CUT FLOWERS.

WHERE it is desired to keep cut flowers for a special occasion, a very good plan is that shown in the illustration. Here, on a flat surface, is spread a layer of damp sand about 2ins. deep. The stalks of the flowers are pushed into the sand and the whole is then covered with a glass shade. In the case of small flowers, empty jam-jars inverted over the blooms would do well. Keep the whole arrangement in rather a cool place, where there is no risk of frost. Examine now and then and moisten the sand if it becomes dry. Watch for signs of mould, and should these appear clear away at once. To prevent the development of mould it is a good plan to soak a piece of cotton-wool in a formalin solution and put this under the shade. Flowers treated in this manner will remain in good condition for several weeks, as the writer has proved on more than one occasion.—S. LEONARD BASTIN.

HOW TO KEEP CUT FLOWERS.

SPIRÆA JAPONICA AND SOLOMON'S SEAL.

BOTH of these plants are easily forced into bloom many weeks in advance of those specimens left in the open borders. There are numerous greenhouses and conservatories in the country built in partial shade, some of which do not receive any sunshine from November to late spring, and the above-mentioned plants are very suitable for flowering in such structures. Clumps may be purchased from advertisers in this journal now, or, if available in the garden borders and are strong, they may be lifted forthwith and potted. The fact that the clumps have been exposed to the recent frosts will not matter, as frosts cause rest to the crown and root.

7 GOLD MEDALS AND 2 SILVER TROPHIES To Exhibits of Carters Vegetables during 1925.

SEEDSMEN BY APPOINTMENT

SEASON 1926

VEGETABLES OF QUALITY

THE painstaking care in Selecting, Testing, and Raising only the best varieties of Vegetables is again confirmed in the record list of Gold Medals awarded during 1925 to Exhibits of Carters Vegetables.

It is well to remind our Customers that over 12,000 individual test rows were grown to full maturity in our grounds at Raynes Park during the past season, to compare and examine the merits of each variety at every stage of growth.

This process is carried out each year so that the highest standard of quality is maintained.

We respectfully invite you to inspect our processes by paying us a visit at Raynes Park.

IT PROTECTS YOU AND HELPS YOU!

Advertising does far more than make a bald statement about the goods. At various times it illustrates them, tells you what you want to know about them, tells you where to buy them and how to use them. By illustrating them it protects you and shows you what to look for, by the rest it **helps** you and saves time.

Take a strong garden fork or a spade, remove any loose leaves, but not stems of late flowers or leaves that are firmly fixed to the crowns of the plants, then dig well under each clump and raise them bodily. Remove them to the potting-shed; select pots of various sizes so that the clumps may be potted whole, not divided. It is only necessary to place the clumps in the pots with a small quantity of finely sifted soil firmed around the roots. Apply water and place the pots in a cold frame, packing straw, leaves or soil around them to prevent breakage by frosts. Introduce a few pots to the heated structures each week, simply keeping the roots and soil moist and feed when the new growth is 6ins. high. These plants provide lovely flowers and foliage for greenhouse or dwelling-room.—G. G.

SOIL MIXTURES FOR ALPINES.

ONE of the first steps towards the solution of the problem of successfully establishing our little mountain friends in this often unsuitable climate is undoubtedly to obtain a soil mixture or compost which be favourable for vigorous growth. While I can hardly call this a science in itself, yet a good deal of practical knowledge is necessary before the happy task of "soil blending" can be successfully undertaken. I say "happy task" advisedly, for I have found that many of my happiest gardening moments were spent in composing either a "rich and fruity" or "poor and stony" compost, in which to plant some new treasure of the Alps.

Plants seem to have almost human likes and dislikes, and I believe there is much more individuality among them than is generally supposed, for while there are certain broad rules laid down as to "lime lovers" and "lime haters," etc., which must not be forgotten, yet I have often found that one may transgress upon these rules considerably, and often with notable success. In fact, I may add, that it is becoming a passion of mine, inasmuch as, if I am given a plant with a solemn warning as to its rabid hatred of lime, I immediately wish to try it in a lime mixture. Of course, I cannot claim success in every instance, for I am afraid that I have had many dismal failures, and have learnt *never* to experiment while only possessing one of a variety, or it will surely die, but when one has two or three it is very interesting to experiment (and, incidentally, I suppose, to prove other folks wrong).

I find that great success can be attained with a lot of the rarer androsaces and the lime-hating saxifrages (of which last there are very few) in a soil composed largely of broken-up roofing slates, but as I described this method fully in these pages some time ago I need not linger over it longer than to say that since my previous notes, I have amply proved the success of this method.

Another mixture which seems to be a very general favourite is one containing quantities of finely broken sandstone. It should be smashed into pieces about as large as peas, and all the sandy dust added as well. The plants seem to have a special affection for this, and one finds their roots twined lovingly round the little knobs of stone in a very short time, as if drawing hearty sustenance therefrom.

Most of the lime-lovers will do almost equally as well in a lime-free soil, but if a plant really is averse to lime, it is useless to place it where its roots can find it, as it will soon begin to look yellow and unhappy.

A very successful method of growing such members of the ornata group of gentians as G. sino-ornata, G. Farreri, etc., is in a compost made up of coconut fibre, silver sand and a little fibrous loam. In this they thrive steadily, without any of that "yellowing" so apparent when their roots are finding too much lime.

To return to the individuality of plants which I mentioned at the commencement of this article, strangely enough I have often discovered that individual plants of the same variety will give finer results under different treatment. I do not know why this should be so, or why, if one plant of Dianthus alpinus should be happy in a pan of limestone chips, his brother should not be equally so. The late Reginald Farrer was not far wrong when he said that no two plants out of the same seed-pod had exactly the same character or requirements.

I could go on for long about this interesting subject, but I have said sufficient to show that a lot of our little friends need a certain amount of pandering to their likes and dislikes.—W. INGWERSEN, JUN.

VEGETABLES

BRUSSELS SPROUTS: AN EARLY START FOR QUALITY.

IT is acknowledged that no vegetable pays better for a long season of growth than Brussels sprouts, and for a liberal amount of space for development. To this end it is advisable to sow a pinch of seed in the warmth of a greenhouse towards the end of January, pricking out the seedlings as soon as they have got well into their second leaf, and placing the boxes in a cooler structure until one may safely shift into cold frames. March and April sowings never "catch up" plants from the earliest batch, and the latter by October unmistakably show the advantage of a good start by the quality of the sprouts. At least a yard apart should be the minimum, and the ground ought to be in good heart by deep digging and incorporating with it leaves and vegetable refuse. I have had good results with this form of manuring alone, and am inclined to the belief that it often equals animal manure, which, in these days, is difficult to procure at anything like a reasonable cost. I am convinced of the great advantage there is in starting early in the year with Brussels sprouts.—CLAREMONT.

EARLY LETTUCES.

EARLY lettuces are always much appreciated, but it is sometimes difficult to grow specimens with fine hearts early in the year. The right varieties should be selected, those of the cabbage section and not those of the cos. It does not matter about size. Early growth of central leaves; this does matter. I daresay some readers have special favourites, but the following are almost certain to please: Tom Thumb, Early Paris Market, followed by All the Year Round. We begin by sowing a few seeds in a large box, long and wide, not more than 6ins. deep. The box should be filled with a rich compost, rotted manure and half-rotted leaves to form the bottom layer, then old chrysanthemum soil to fill up. If the latter is not available, use good loam and leaf soil in equal proportions, with a free addition of rotted manure — none is more suitable than old mushroom bed manure. The boxes being filled, and the soil in them levelled, water should be applied before sowing. Drop the seeds very thinly—about 1in. apart, if possible—cover with a very thin layer of dry soil. Do not water this. The seedlings will soon appear in a warmed frame or greenhouse. In the meantime, prepare a few more boxes in a similar way, but do not water the soil. Transplant the seedlings to these boxes carefully, leaving some in the seed boxes (distance apart, 2ins. to 3ins.) and fill up holes made with a little fine soil. The undisturbed seedlings will be the first to form hearts and the others will maintain a succession. Keep the boxes about 2ft. from the roof glass.—G. GARNER.

GREENHOUSE

LATE PLANTING OF GRAPE VINES.

GRAPE vines may be planted any time from November to May. In the autumn and in mid-winter the vines are planted in a dormant state. About May they are, of course, in a growing state and very much care is needed to prevent undue drooping of the young leaves. If, however, close attention is given to them, vines planted in May do not receive any check and make wonderfully good progress during the summer months. The border, in all cases, if convenient, should be prepared several months prior to the work of planting if this cannot be done, then the turf used should be quite three months old, that is, it should have been cut and heaped for a period of three months. I am now dealing, mainly, with the work connected with the planting of growing vines, as there are cases where this is absolutely necessary, or a wait of a year must ensue. All borders for early and late vines, respectively, should be inside; those for intermediate varieties may be partly inside and partly outside, the vines being planted inside. The depth of the border should be, approximately, 3ft., including 9ins. of drainage. Whole turves should be placed on the drainage, the remainder being chopped, but not too finely. Add old mortar rubble and finely-ground bones to the mixture; use the latter in a dry state and tread it firmly. The young growing vines must be carefully turned out of their pots, the main roots spread out and all buried 4ins. deep. Apply water to the roots, and shade to the foliage for two weeks. A daily syringing will help the vines, too.—HANTS.

MISCELLANEOUS

PROPAGATION OF SOFT-WOODED PLANTS.

QUESTION.—Will soft-wooded plants, rooted after Christmas, be suitable for bedding-out in the following summer?

Answer.—Yes, many thousands of plants are so raised every year from cuttings. It frequently happens that the autumn-struck stock is inadequate to meet the ordinary requirements of the flower gardener and so he must then depend upon plants raised from seeds sown in spring or cuttings propagated early in the New Year. Old specimens or autumn-struck plants are specially prepared for the supply of these spring cuttings. In the ordinary way the plants are retained in a very moderate heat so that they will be stocky in spring. But, for the supply of cuttings, they are subjected to a higher temperature—one approaching to summer heat—then young shoots grow quickly and these, when severed with a sharp knife, prepared and inserted in a light, sandy compost, soon form roots, especially if there is a little bottom heat available. The majority of such cuttings, those of heliotrope, lobelia, ageratum, iresines and coleus are inserted round the sides of large pots, but ivy-leaved and zonal pelargoniums are best inserted singly in small pots.

Question.—Why should this difference be made?

Answer.—Because the first-named, and others somewhat similar, form roots quickly and it is possible to re-pot or box the young rooted plants prior to their final planting out. The pelargoniums root more slowly so they should not be disturbed, but allowed to remain in the cutting pots till they are, with the others, gradually hardened in cold frames and planted out early in June.—CHRISTCHURCH.

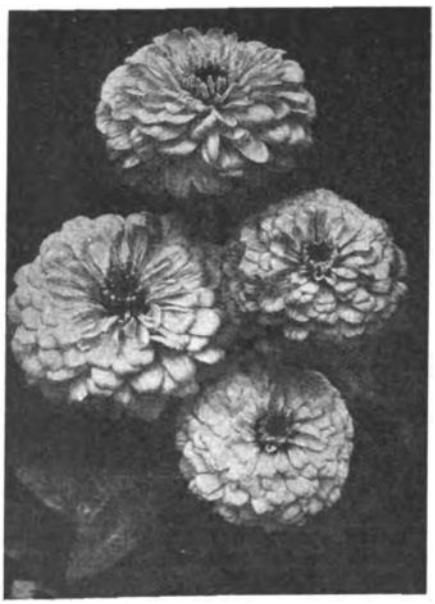
DAHLIA FLOWERED ZINNIAS.

ZINNIAS have been greatly improved during the last seven years, but among all the new varieties the giant dahlia-flowered kinds are of outstanding merit. As the name implies, they are not unlike the decorative dahlias; in rich soil they will grow 3ft. in height and the flowers, averaging 4ins. in diameter, may at times reach 6ins. The colouring is gorgeous; reds and crimsons of various shades predominate, but there are yellow, orange, purple and white zinnias to be had. Indeed, we feel sure that when the newer sorts become better known, their popularity will increase. Seed must not be sown too early; the first week in March is an excellent time to sow. The ground must be deeply



dug and liberally manured in advance and the plants must not be put out until well on in May.—HUGH AITKEN.

PRIMULA SINENSIS.

NO lover of his greenhouse will ever be without primulas. Few plants can surpass them for winter decoration. Their cultivation is comparatively easy. The seed of the sinensis varieties should be sown in heat about the middle of February. As germination is rather slow, attention should be given to the pots or pans containing the seed, in order that they do not become dry. To prevent this a sheet of glass can be placed over them, at the same time shading with paper.

Some time in May the seedlings should be quite large enough to place in 2in. pots, any good potting compost being suitable. After they are potted place them in a frame—one

UNWIN'S SWEET PEAS

Known and grown all over the World. There are no Sweet Peas of better quality obtainable. You will eventually grow them, why not *this* season?

having a coal ash bottom is preferable—and then give a watering and shade from bright sunshine. As soon as the plants become established, give air on all favourable occasions. In two months time from date of potting the plants should be ready for another shift. This time 5in. pots will be required, being the most suitable size in which to flower the plants. After re-potting is over set the plants back into the frame, and give the same attention as before. Always keep the plants as near the light as possible, and give them plenty of room. When they are well established, dilute applications of liquid manure may be given two or three times a week. With this treatment good strong plants should be obtained. They will commence flowering in December, and from then on to the end of February should keep

the greenhouse bright. The two best varieties to grow are Sutton's Royal White and Crimson King.—DAVID ARMSTRONG.

TWO BLUE ANNUALS: PHACELIA CAMPANULARIA AND DIDISCUS CŒRULEUS.

LOVERS of blue flowers and those who like to grow unusual plants may perhaps be glad to be reminded of two of these before they send off their order for next year's seeds. Both are annuals and, unlike most annuals, both look quite at home in sunny dry pockets of the rock garden. P. campanularia is known to many garden enthusiasts, but it is still ignored by the vast crowd of garden owners, and cannot be obtained save direct from the seedsmen. Yet this little gem is unrivalled among annuals, both for its compact habit and for the deep blue of its gentian-like flowers and its attractive brown leaves. It begins to flower so soon as Gentiana acaulis finishes blooming, and, if planted as an edging, will replace that favourite during the summer months. The phacelia may be sown every ten days from April to September and in the last fortnight of the last-named month, to ensure its blossoming early in the following year.

This little annual does not like being transplanted.

The phacelia is a native of Carolina and belongs to the hydrophyllaceæ order.

Didiscus cœruleus, otherwise known as Trachymene cœrulea or Huegelia cœrulea,

Austins
Scotch Seed Potatoes.

Our stocks are grown and selected specially for seed purposes, and under normal conditions of soil and situation cannot fail to produce first-class crops. All are Class 1, Scotch.

MILBURY HEATH, FALFIELD, GLOS.

Please mention THE GARDEN *when writing.*

is an annual which is practically unknown in Britain. Its seeds can be obtained from some French seedsmen, but, although it was introduced into France from Australia nearly a hundred years ago, it is very rarely met with in French gardens. This blue hugelia is an umbelliferæ, which adds to its rarity, blue being a most unusual colour in plants of that order. This plant has a branching habit and is about 1½ft. high, the flowers being pale blue and the leaves tripinnate with serrated lobes. It seeds freely, but as it is only half hardy, the seeds should be sown in a sheltered position in the open in May, and the seedlings transplanted as soon as they are sizeable.

The surest way of securing strong plants of Didiscus cœruleus in abundance is to sow the seeds in a cold frame or in boxes in the greenhouse in February and March, potting up the seedlings into sixties when they are a few inches high and putting them into their

DIDISCUS CŒRULEUS.

permanent quarters when all danger of frost is over. Seeds can also be sown in boxes of finely sifted soil and placed on a mild hot-bed.

Didiscus cœruleus requires rather careful culture. It prefers a light friable, well-drained loam. Damp heavy soil is unsuitable, and, particularly in its early stages of growth, this plant dislikes excessive moisture. D. cœruleus produces its attractive blue flowers in great abundance from August to October. It is a most useful and uncommon annual which is equally suitable for the annual border, for patches in mixed borders, or for bedding.

It would be interesting to try growing the blue hugelia as a greenhouse plant for the winter. It should succeed well if treated like balsams, clarkias and other annuals which are grown for winter decoration. This umbelliferæ requires a rich, light compost and needs very little watering.

Phacelia campanularia and Didiscus cœruleus would make a charming group if they were planted near to each other in the blue border, the phacelia growing in a wide stretch in front of the border, having behind it the feathery foliage of the huegelia, forming a delightful background for its deep blue bells.
—VICTORIA SLADE.

Seedlings Thrive and Don't Die

off after being transplanted owing to root disturbance or breakage, if brought up in Patent

MILLIONS SOLD **T. P. SEED RAISERS** NO SLUGS

because no disturbance can take place.

FOR ANNUALS, as Godetias, Clarkias, Larkspur, etc., *USE* BABY T.P. SEED RAISERS (measuring 1¼in. across by 2in. deep). Sow 2 or 3 seeds per Raiser, pull out to strongest. It will develop strong root growth till planting-out time comes, when Raiser (by that time rotted) will peel off, allowing seedling to be put in soil without knowing it has been touched.

FOR SWEET PEAS *USE* T.P. PEA RAISERS (size 1¾in. across by 4¼in. deep). Sow 1 seed per Raiser. You will be delighted with good root action and quick development after planting out.

You get stronger plants, guaranteed to grow well with less labour.

T.P. Raisers take up much less room and retain moisture thus requiring less watering, are easy to handle in bulk and do not break, and ensure good plants, thus saving seed wastage.

PRICES in U.K., cash with order, carriage paid—

"Baby" T.P. Seed Raisers, one strong seedling tray with 54 "Baby" Raisers complete. 1 for 2/6; 2 for 4/9; 3 for 6/9; 6 for 13/-; 12 for 24/6. **Refills** ("Baby" size), 108 for 2/7; 216 for 4/10; 324 for 7/3; 540 for 11/3.

T.P. Pea Raisers, one wooden box having hinged side with 48 Raisers complete. 1 for 4/3; 2 for 8/-; 3 for 11/6; 6 for 22/6. **Refills.** Pea size, 100 for 3/-; 200 for 5/9; 300 for 8/3; 500 for 13/6

Order NOW from your Seedsman. If he does not stock, send direct to Sole Makers

FURTHER NOTES

ONE fact that I did not draw attention to last week was the extraordinary way in which the late mingling of snow and frost has lifted plants, particularly seedlings of shallow-rooting genera like rhododendrons, and has thrown them out on the surface. I found a clump of R. moupinense carefully deposited on their side; not that this causes serious damage, provided that they are replanted at once. This lifting is often put down to bad planting, but that is not the case, for rhododendrons, particularly, should be planted so that the stem immediately above the first layer of fibrous roots should get light and air. It is only natural in the case of seedlings which are manufacturing their tangle of tiny roots as quickly as they can, that the slightest lifting of the soil will upset their balance and over they topple. The frost this year has exerted a remarkable action in Scotland, at any rate, and the earth skin that has broken away has been more solid than usual.

In all other respects the rhododendrons have suffered as little as other shrubs. A few twigs have certainly been broken, but I can find no frosted flower buds with the exception of those on R. decorum; but as this has happened during the past three years I cannot put it down to the present severe weather. The truth is that R. decorum is a widely spread plant in Upper Burma, Yunnan and Szechuan, with great variation in altitude and that some forms are hardier than others. I am sure that I am unlucky and that mine comes from a low altitude, for it is planted in an admirable position by the burnside where it is absolutely sheltered from wind. It is a pity, for R. decorum is a beautiful plant with its solid foliage, its free-flowering habit, and its pearl white flowers. I must again point out the advantage of R. ciliatum as a plant for the most exposed and windswept position in the rock garden. So far, most lovers of this Himalayan beauty have been frightened of it and have coddled it, perhaps because it belongs to a series that has given us R. ciliicalyx and other greenhouse rhododendrons. It was at the Edinburgh Botanic Garden that its absolute hardiness was first proved, and I can now qualify their experience by my own, for I have it planted in full sun in a dry position; the bushes are sturdy and squat and each is set with flower buds that are absolutely unharmed by eighteen degrees of frost. It is really an invaluable plant, both for its beauty and for hardiness.

A curious fact has come to our notice here regarding the long life of snowdrop bulbs. A few weeks ago we cleaned the ivy off a precipitous rocky bank; not a few straggling tendrils, but a solid mat of leaves, branches and roots a foot thick. This, to our knowledge, has certainly been of the same density for the past twenty-five years. Within a month of clearance snowdrops have come up in solid clumps in almost every pocket of earth and are already 3–4ins. high. This is not the case of the survival of an odd bulb or two, but of hundreds, that have certainly not shown a flower for twenty-five years. It would be interesting if any reader of THE GARDEN has had a similar experience, or if anyone can say how long a snowdrop bulb can remain in a cataleptic state.

In a wood that has been partially cleared to form a wild garden I have had a good experience of the weeds that spring up on ground that was heavily shaded. The first to appear was Epilobium angustifolium, the fine weed which, besides being highly ornamental, is comparatively harmless. The crop last year consisted of Ranunculus Ficaria, the lesser celandine, a crawling pestilential terror that chokes everything in its path, and Campanula latifolia, that, for all its beauty, is a bad plant in a wild garden, for its root stocks delve deep into every crack and cranny in the rock and are exceedingly difficult to remove. On the other hand, its height makes it easier to deal with than the ranunculus, for which I know no cure. In time, of course, shrubs will produce sufficient shade to keep it in check, but it means constant weeding around the plants. By the waterside, too, Chrysosplenium oppositifolium has gained a footing, but the green carpet of this saxifrigaceous weed is so pleasant and restful in colour that I have not the heart to tear it up. E. H. M. C.

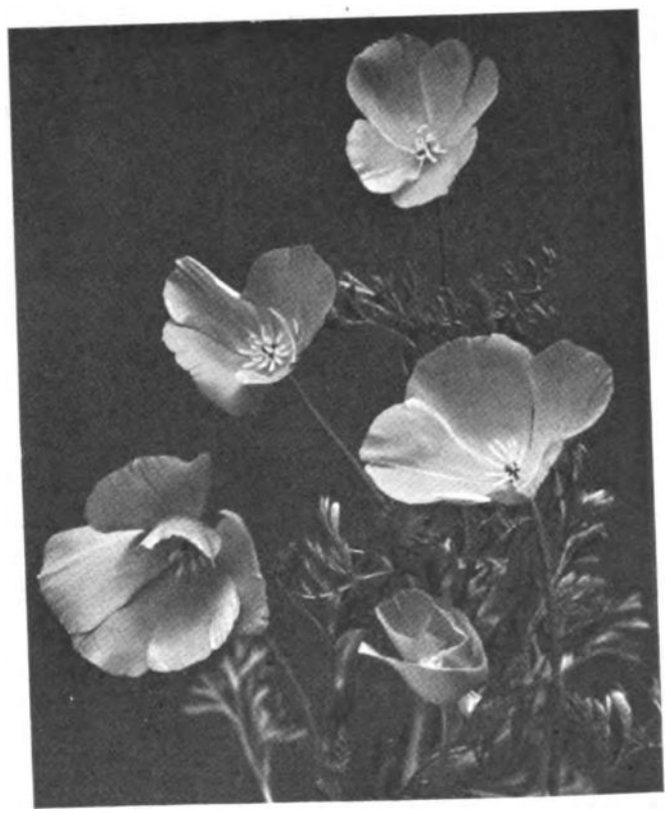
SOME ANNUALS OF DISTINCTION

IF I am one of those who possess a garden which does not lend itself to the growing of annuals on an extensive scale for colour effect, I am not one to turn up a contemptuous nose at a plant because it is an annual. On the contrary, it has become a habit these many years to indulge in a few packets of seed every season, including not only those plants which have proved their merit and won my affection, but others which I had not hitherto tried. The lists, like the world, are so "full of a number of things" that one cannot in a single season, or in a dozen seasons, become acquainted with them all, so I earmark a few each year, and thus, in the course of time, I get to know something of the multitude, and out of these select a few as special favourites for regular sowing.

In referring to some of these latter individually, one which always goes into any list is Omphalodes linifolia, a slender, glaucous-leaved plant of some 10ins., with large flowers of that curious icy whiteness which is often so telling. For a partly shaded situation a group of O. linifolia is always delightful, sown in spring where it is to come to maturity. It blooms all the summer and autumn, often sows itself in future years, and rarely does otherwise than well under any conditions.

The annual toadflaxes are of a somewhat similar style of growth to the above, making lovely waving masses of upright, elegant stems of about a foot which yield fine heads of flowers for many months. In species and varieties there is a wide choice, the colour ranging from pale rosy lavender to deep purple, from a lemon yellow to rich orange. Linaria maroccana will give blossoms varying from rose to violet; L. bipartita is the lucky-bag of the family, with an even greater assortment of pretty colours, including a white. Then there is L. multipunctata, perhaps the most charming, as it is the most dwarf, of all, its little snapdragons being a velvety black with their "noses" distinctly speckled with gold. Even those who brandish flaming swords when perennial linarias threaten to enter their gates can sow these pretty, well behaved, good-tempered annuals and sleep soundly in their beds. We simply scatter a little of the seed thinly in patches in any spare sunny place and cover with a little sand or fine ashes.

The purslanes, as a race, are rather apt to be garish in the matter of colour—that is, when they do it at all (mine are usually dead), but Calandrinia grandiflora is a superbly beautiful annual which no one can afford to omit. Rising from a bold rosette of fleshy, pinky-glaucous leaves, the 18in. flowering stems of the same hue branch freely and bear throughout the late summer a succession of rose pink blossoms, round as a florin, and centred with a cluster of golden anthers. These lovely blooms are a good, clear rose pink, and few things can be more attractive on a dry, sunny ledge or forefront of border than this stately plant.



DEEP ORANGE ESCHSCHOLTZIAS PRODUCE A BRILLIANT EFFECT FOR MANY WEEKS.

A CLUMP OF HYBRID LEPTOSIPHONS.

There are some excellent annuals among the pimpernels, and if Anagallis linifolia (grandiflora) often suffers from too much familiarity, it is, especially in the deep blue form, one of the best of subjects in this class of plant for edging, massing and like purposes. The lasthenias, daisy-flowered natives of California in distinctive shades of yellow and orange, are also first-rate in bold masses, and, like the foregoing, spring-sown plants will be very gay in the late summer when many flowers are going off. So much and more may be said of the bright little leptosiphons. Of these my own preference leans towards the dwarfer kinds, to LL. rosea, aureus and the hybrids offered in most good lists. In colour these afford cheerful shades of carmine and rose, orange and buff, and my plan with these is to get a few packets of seed and to scatter their contents in pinches in the chinks between the stones of rock garden, steps, paved walks and walls—always in full sun.

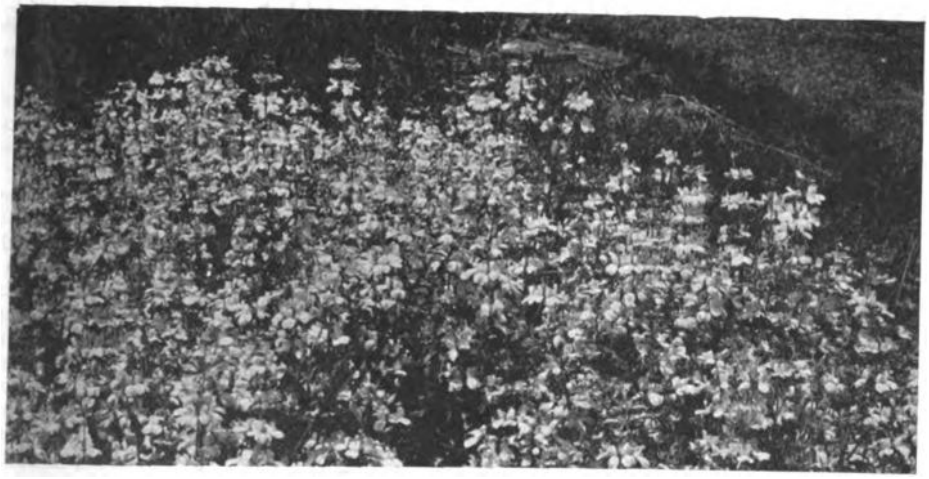
The nolanas, or Chilian bellflowers, give a good account of themselves as trailing annuals for the front of a sunny border or the rock garden, and these, again, may be sown where they are to remain. The best is, I think, N. atriplicifolia, which bears sumptuous white-throated, violet bugles, suggesting a small gloxinia and often rivalling the better-known phacelias in the richness of their velvety hues. The aforementioned lasthenias go well as a background to the prostrate nolanas and phacelias, or, in default of the former, one must go in for those exquisite little eschscholtzias, EE. cæspitosa and tenuifolium. These make neat upright tufts, 6ins. high, of finely cut glaucous leafage, and maintain an amazing succession of pretty saucer-shaped yellow flowers well into autumn Strictly

Digitized by Google

speaking, these are probably no more annuals than are their bigger relations, but, as with the latter, they may be treated as such.

I have a warm regard for the collinsias, because they are so easy and bright and willing to make themselves useful in a variety of ways, if not among the choicer annuals. For example, if we have made a new plantation of heaths or brooms, or if there is any other sunny plot that needs a covering crop which will be very gay as well as helpful in keeping down weeds and cooling the burning earth, the collinsias are just the thing to achieve that end. There are several kinds listed, such as C. bicolor, in purple and white; grandiflora, blue and white; and the blue insignis. These are rather under a foot in height, and the flowers are large and yielded in the greatest profusion. For such purposes as the above we sow broadcast in spring and merely rake in the seed, sometimes adding a few packets of Mentzelia (Bartonia) aurea, which is rather taller and whose fine blooms are a glistening treacle-gold.

A very beautiful and unusual crucifer for a warm, good soil is Schizopetalon Walkeri, which grows to about 1ft., adorning its fringy lacework with almond-scented squares of white which are uncommonly effective. As this transplants badly, it should be sown in early May where the plants are to bloom. For the edge of a dry border on any hot, sunny place the 6in. trailer, Venidium calendulaceum, with its large glowing orange marigolds, can be very satisfying. This, I find, is best raised in gentle heat, and the same, of course, applies to the dimorphothecas, which never fail to make many friends. D. pluvialis, which bears yellow-centred, white-rayed daisies backed by maroon, is, perhaps, the most attractive if not the best known.



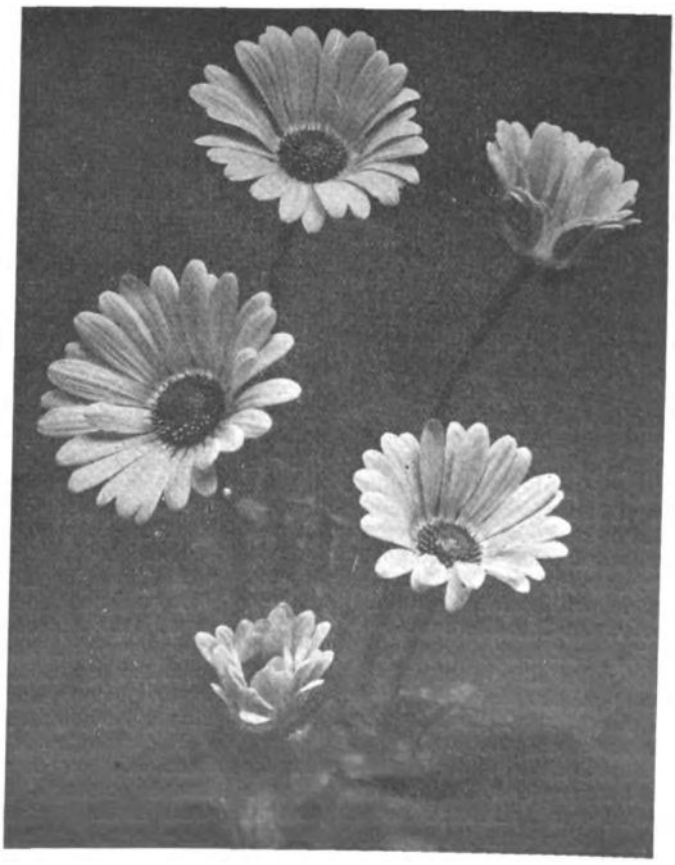
ONE OF THE BRIGHTEST AND MOST ATTRACTIVE OF ANNUALS, COLLINSIA BICOLOR.

The Mexican, Hunnemannia fumariæfolia, is a perennial but it makes such a good annual here in the west that I am induced to include it in this selection. It is related to eschscholtzia, but is taller and more upright; the foliage is extremely elegant and glaucous, and the very large orange-yellow flowers, so like those of Dendromecon rigidum, the tree poppy, are fragrant and last for several days. In a dry, warm border I raise this plant from open ground sowings made in May. The seedlings move badly. A colony grouped behind a pale blue form of nigella makes a very telling effect.

With a mention of nemophila my very incomplete list must end. Albeit, I am not so sure that these Californian bluebells are not the good wine of the feast, for, in spite of their commonness, they are singularly lovely and, what is more, as easily grown as groundsel. The N. insignis section is still, perhaps, the most admirable; but there are many other excellent species and varieties, not forgetting the remarkably beautiful N. atomaria atrocœrulea, which is as easy as any other and whose blue can rival that of the bluest of phacelias.

A. T. JOHNSON.

THE ORANGE-COLOURED HUNNEMANNIA FUMARIÆFOLIA.



THE GLOWING FLOWERS OF VENIDIUM CALENDULACEUM.

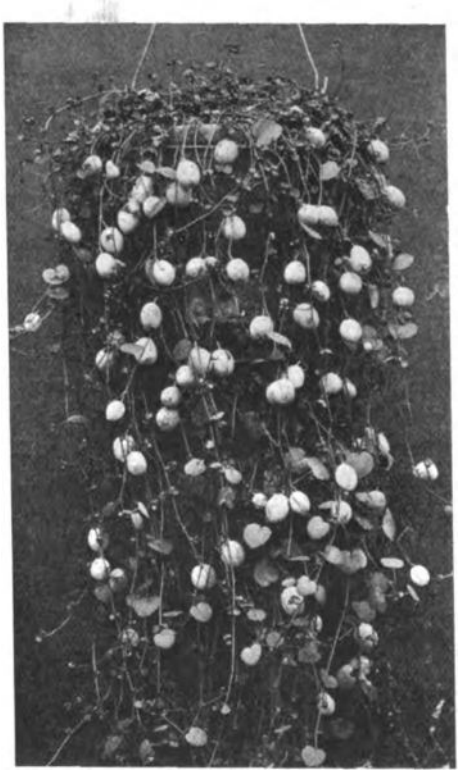
FUCHSIA SPECIES AND THEIR VARIETIES

IT is greatly to be hoped that the revival of interest in garden hybrid fuchsias will include the wild species and their numerous varieties, comparatively few of which are in cultivation to-day, and most of these are rarely seen outside botanic gardens. In the south-western districts, where severe frost is seldom experienced, fuchsias play a prominent part in the adornment of the garden throughout the summer; in colder districts most of them require the protection of a cool house—at any rate in winter. A collection of wild types of fuchsia would prove of considerable interest and would appeal to many plant lovers who cannot muster any enthusiasm for the large double greenhouse varieties, which have lost all the natural grace of the wild species.

By far the most generally grown fuchsias outdoors are the many forms of F. macrostemma, which is probably one of the parents of the invaluable F. Riccartoni, the hardiest of the genus and one of the best for hedges. In the plant which appears to be typical F. macrostemma the scarlet lobes of the calyx are larger than the purple petals, whereas in F. m. conica sepals and petals are of equal length. Both forms make rapid growth in rich soil, stiff, upright shoots 6ft. in height being sent up from the base. These two forms are slightly more frost-tender than F. F. m. gracilis, Riccartoni and globosa. F. m. gracilis is distinct in its elegant arching habit and long slender flowers of the typical fuchsia type; there are several varieties of it with more or less purple in the leaves, as well as a very attractive variegated form which is much slower in becoming a big bush. F. m. globosa is another fairly well known variety, characterised by its stiff habit and large, round flower-buds. F. m. pumila is a dwarf form of compact habit, excellent for planting on a rock garden or at the front of a shrubbery. F. corallina (or F. exoniensis) is apparently yet another variation of the macrostemma group. It is frequently seen in the West of England hanging over low walls, a position well suited to its semi-scandent strong-growing habit. There is a good deal of purple in the leaf and the flowers are 1½ins. long with prominent red stamens. A number of garden-raised varieties in shades of red and white, purple and pink and white, and red and purple, both single and double, may be seen in cottage gardens in many villages near the coast, but their names are generally long since forgotten. Several of these are mentioned in Mr. Cahen's article on fuchsias which appeared recently in THE GARDEN.

The remaining species of fuchsia are mostly less hardy but more interesting owing to the infinitely greater variety in their flowers than in those of the macrostemma group.

F. cordifolia grows into a shapely bush some 5ft. or 6ft. high and as much in diameter in sheltered Cornish gardens. When laden with its scarlet and green flowers in April and May it is a magnificent sight and a revelation to those who only know it as a pot plant. F. corymbiflora is another noble shrub, bearing bunches of long narrow-tubed scarlet blossoms at the tips of the long branches. It is a Peruvian species and is much better suited for a large greenhouse than for outdoor cultivation. F. Cottinghamii is abundantly distinct with its myriads of tiny scarlet flowers which are interspersed with round, glossy, black berries in autumn. It soon forms a slender bush 6ft. or 7ft. high in sheltered gardens, but is liable to be severely cut back by hard frosts. The somewhat similar F. reflexa is more



TINY FLOWERS AND LARGE MAGENTA BERRIES OF FUCHSIA PROCUMBENS.

hardy and equally charming with its tiny rose-crimson flowers and white stamens; it forms a dense, twiggy shrub about 5ft. high and is rarely damaged by frosts on the West Somerset coast; indeed, it is very seldom out of flower.

F. arborescens is a rose-coloured fuchsia attaining the dimensions of a small tree in Mexico. It might succeed in the open in very mild districts but I have never seen it. F. venusta is another very distinct and beautiful species bearing numerous red flowers with green sepals about 1½ins. long. It is tender and is often cut to the ground level, but it breaks again in spring and the young shoots flower in the autumn. If planted against a wall, preferably where it can grow through some protecting shrub, it will soon attain a height of 10ft.

F. triphylla is a handsome plant from Mexico, more familiar in greenhouses through its hybrid offspring than in the typical form, and the same may be said of the Mexican F. splendens.

The three New Zealand fuchsias cannot be called showy plants, but they are all of considerable interest. The largest is F. excorticata, generally hardy in the south, a strong-growing shrub with us, but a timber tree in its native land. It has curious small purplish flowers (often produced close to the main branches) in spring and sometimes again in autumn. There are three forms of flowers in this species, *viz.*, a long-styled female form, a mid-styled and a short-styled form, the two latter forms being hermaphrodite flowers. The pollen in all the New Zealand fuchsias is blue (instead of the usual yellow or white) and very viscid, an adaptation to aid pollination by insects, as the flowers are neither gaily coloured nor scented. F. Colensoi is a much smaller plant, only about a foot in height. The third species, F. procumbens, is a favourite pot plant in greenhouses and succeeds well outside in fairly sheltered and preferably shady situations. It appreciates peat and leaf-mould, and soon forms a pleasing carpet of wiry stems of green foliage sprinkled with curious little flowers and large magenta berries.

SOMERSET.

NOTES ON A ROCK GARDEN

ALL day long between the autumn showers I have donned my clogs and hastened to the garden. For years I avoided a rockery near this house. But the catalogues and memories of days gone by were too much. Some plants I very much wished to grow, and at our little place on the moors they would do right well, but we cannot live there all the year and people hunt round in our absence and help themselves.

Slowly and by all sorts of means I have collected some beautiful weathered freestone rocks from the high moors. At odd times I have brought back baskets of leaf-mould from the oak wood, and peat from where the sky meets the moor on Swainston Crag. By peat I do not mean the dark slabs of black peat, through which no air can pass and in which no worms can live, full of dangerous acids which grip plant life and convert it to "fat moor," but what are best described as "flaughts," which is nothing more than moorland sods full of humus and light soil together with layers of decaying bracken and small roots of ling.

I learned my lesson about peat some years ago. The "W.M." is very fond of carnations, so I set out to grow some, wireworm played havoc. I knew that garden pests could not grow in peat, so I dug some real black peat and mixed it with silver sand in a raised bed on the moors. I had to return here for a spell. Instead of flourishing carnations when I went back, I found dead plants in an unbreakable cake of peat. A potato field near our eyrie residence yields wonderful crops, because it was reclaimed from peat moor long years ago, but there is now no trace of the black sad stuff that keeps us warm in winter.

To go back to my rock garden. First I made a high mound of soil (where a

Digitized by Google

flat, clay, sad herbaceous border used to be) running up and down and in and out right round one side of the lawn. Then the rocks were thrown on, not so much for effect but to make nooks for each set of plants, each stone well buried in. In one cosy corner Grecian windflowers were planted next to groups of tender-hued daffodils. The definite yellows of these trumpeters flower in the shade of a beech hedge, which keeps its warm-looking leaves through the winter, till the young shoots push them off in spring. High up in a gritty mixture "Angel's Tears" have settled in. The "Glory of the Snow" is planted on a slope till it reaches down to a drift of polyanthus of lovely sunset shades snuggled in rich loam. A small boulder decides the next corner and supports a sandy slope, the abode of Anemone fulgens. Farther round and down to a richer corner is a group of dwarf rhododendrons. Then, best of all, round another rock is a healthy young plant of Gentiana sino-ornata. I hope it spreads and multiplies well; it is a lovely thing. Gentiana Farreri died. Above, on the slope, are drifts of crocuses—Tomasinianus, biflorus, Sieberi, Imperati and a group whose name I have forgotten; on into tufts of hepaticas, oh! that I had more of them. They are memory flowers. Daphne Blagayana has settled on my first attempt, and I am overjoyed, for I lost Cneorum straight away. I do wish nurserymen would send us poor amateurs pot-grown plants of these difficult-to-settle shrubby species. Cneorum looked doomed when I unpacked it, roots not kept damp, sprawly and dry, as if it had been pulled up out of the garden and forgotten on a potting bench. Snowdrops Elwesii complete this corner, companioned by a lovely thing that looks like an escaped water lily which throws off a delightful perfume in the evening like the evening primrose. Oh! and duck's-foot next to a plant that looks as if it is related

SNOWDROPS FOR THE SPRING.

to Solomon's seal with yellow flowers. Primulas hold first place in my affections, and they know it, judging by the hearty way they grow. So far, however, I only have the easy-growing sorts, the new garden will hold the rarer and more difficult beauties.

A small group of Primula Littoniana was a great delight this summer. Some years ago I saw it in the Royal Show at Darlington sitting at the water's edge of Messrs. Kent and Brydon's exhibit. I asked the man in charge how to grow it. He said, "Keep its feet wet in summer and dry in winter." When some plants of it came along I hunted for an old tin that would hold water. In it I put some freestone chunks and lumps of peat with river sand at the bottom and filled up with rain water. I planted the primulas in a rocky nook behind the sunk tin and laid a peat turf as a connecting link between the tin and the roots of the primulas. No sign of the tin was to be seen except that a few strands of sphagnum moss brightened up and showed that there was some hidden moisture about. The plants flowered well. When autumn came I removed the tin and threw gravel and chips into the hole. I am told they are biennials—more's the pity (not gravel and chips!)

I am consoled. Last year a tiny root of Gentiana sino-ornata was sent to me. It has increased and is now creeping up to the place where the tin was. No flowers appeared this year. I wonder if the diet is too rich. I have just trenched on three sides of it and thrown in mortar rubble among the peat, leaf-mould, loam and sand. I am beginning to think that the whole garden would be better if I treated it all alike in the matter of small stones. There are quarries on the moors where the *débris* is thrown out; rain washes it down, where it is left in silt heaps. I bring back baskets of this when possible.

The other primulas I have are denticulata (the white form, too), capitata, Mooreana, sikkimensis, helodoxa and one root of P. rosea. I have seen a brilliant form of this in a friend's garden. Some day I might be fortunate enough to raise a seedling of such a glorious shade. Ruby crimson Juliæ brightens up a shady corner, and Lilac Queen, another hybrid from Juliæ, is cool and beautiful. Dotted all about are restful oxlips with a perfect cowslip form of drooping flowers and slender leaves.

Some of the Primula japonica hybrids are lovely and easy to grow. I have colonies of them in different parts of the garden. Aileen Aroon is a joy near a splash of cool helodoxa. I have often wondered if some of the primula forms have influenced Chinese architecture and some of the head-dresses worn in that country. FLORA DYSART.

NOTES OF THE WEEK

UNUSUAL FORM OF TRILLIUM GRANDIFLORUM (THE NORTH AMERICAN WOOD LILY.)

IN the peninsula of Western Ontario there is a considerable area bordering on Lakes Erie, Ontario and Huron, in which this plant shows variations that are entirely outside the limits set by the authorities. In 1924 I visited a wood where the aberrant forms are numerous and brought home a number of them, which I planted without record, and was surprised to find that some of them were more nearly normal the following year. This incredible state of affairs led me to visit the same woods again on May 10th, 1925, and I am planting some of them in my garden, taking careful note this time of their individual characteristics.

Normally, this species has a six-angled ovary, but only one of all these plants conforms to that detail, nearly all the others having three-angled ovaries, although a few of them have none.

The normal leaf of this species is almost sessile, and there are only three of these that are quite so. Of the twenty other plants referred to here which should have sessile leaves, nine have petioles of ¼in. or less, while one has a petiole about 1in. long, and five vary from 2ins. to 4ins. Then there are three amazing plants that have no leaf at all—nothing but the sepals and petals all in a group. These variations come almost constantly on the plants which depart from the custom of having white flowers, there being only four plants in the whole series that have white petals, the rest having a varying proportion of green, sometimes only a thin light strip down the centre, others have the strip wider and wider until finally the green reaches the edge, and then the end of the petiole is the only part that shows white, and even this sometimes vanishes. It will be an interesting experiment to try to raise seed from some of these forms, but seed is not frequently met with. I have now in the garden one clump from last year's planting which grew all together in the woods as though the plants resulted from one pod of seed. This group not only shows both sessile and stalked leaves, but also pure white and green and white flowers. The shape of the leaves varies also; some of them are narrow and others nearly round with an acuminate tip.

If I am not inundated with requests for these plants I shall be glad to send a few of them to any of your readers who may be specially interested. This would be in the summer, as I have no stocks laid aside for this purpose, and I would go down to the wood, which is about thirty miles from here, next May, when the plants are in bloom, and select the particular aberrant forms that were desired by my correspondents. I would then bring these home, plant them in my garden and leave them there until about August 1st, when they will be ripe, and then mail them to England. I know a good many of your readers are much interested in exotic forms, and as this form is never catalogued, so far as I know, by any dealer, they are unprocurable except from private sources.—W. E. SAUNDERS, *London, Ontario, Canada.*

MUEHLENBECKIAS.

FEW evergreen trailers are more graceful than the muehlenbeckias, which are excellent for covering trellis-work, arches, or for growing as single specimens on old tree trunks. The three species most commonly in cultivation are all natives of New Zealand, and these are hardy, at any rate over large areas of England and even in some Scottish localities. Only in very severe weather is it needful to give a little protection about the lower part of the plant, and for this purpose some dried fern or straw is admirable. Generally speaking, however, the muehlenbeckias will go safely through any ordinary winters. The best known is M. complexa, which is a very rapid grower with long wiry branches and small oval leaves. The white flowers are somewhat inconspicuous, but the whole character of the plant is extremely graceful, and on this account it is at times called the maidenhair creeper. The two other species are M. adpressa and M. varia. The former has relatively large heart-shaped leaves and long racemes of whitish flowers: the latter is very distinctive with leaves shaped like fiddles, the plant as a whole being comparatively small. The muehlenbeckias are very accommodating in the matter of soil, but they grow most rapidly in rather sandy ground, providing this is not too poor. All should be given rather an open position where there is a chance of plenty of sunshine. Propagation is quite easily carried out by means of the thicker shoots that are generally sent up from the ground in the form of suckers. These root very freely in the late spring or early summer, and will be well established by the following winter. People often try to root the twiggy shoots of muehlenbeckia, with very poor results. Even if these grow at all, they take a long while to develop into serviceable plants.—L. B.

A NOVEL METHOD OF ESTABLISHING A FERNERY.

A FERNERY IN A POT.

A VERY interesting fernery can be established in a single pot. Get a pot of large size and round the sides of this bore out a number of holes. The openings should be an inch or more across and they should be separated from each other by about the same distance. The boring of the holes is not so difficult as might be imagined and can be carried out with a brace and an old bit. Actually the composition of the pot is much softer than one might think and it is not at all difficult to grind out the holes. If one does not care to do the job oneself, it is easy to get the work done at a small expense in a builder's yard. With the holes made in the pot one may start to plant out the garden. First of all put some pieces of broken pot in the bottom to act as drainage. Then fill in good soil up to the level of the first set of holes. In these holes insert small ferns and fill in more soil up to the next round of openings. So on in this way until the last set of holes is reached. Complete the planting of the pot by putting in one large fern at the top. All that is now needed is to keep the pot garden in a fairly light position and see that it is well supplied with water. The ferns will grow with great vigour and the whole pot will soon be a mass of beautiful greenery. The novel fernery will last for years and with very little attention will remain a most beautiful room ornament.—S. LEONARD BASTIN.

THE YELLOW SNOWDROPS.

THERE are numerous varieties of galanthus, but among the most interesting are those known as the yellow snowdrops. Here the name is given, not because the petals of the flower are yellow, but on account of the yellow colouring of the ovary and similarly tinted markings on the inner petals. Even the stalks of the flowers are more yellow than green. The two varieties are known as G. lutescens and G. flavescens, and both were first discovered in old-fashioned gardens in Northumberland. The first named is of small size and of delicate constitution and is not so easy to grow as the latter. G. flavescens is an altogether more robust plant, in which the yellow tinting is extremely vivid. If this yellow snowdrop were better known it would be widely cultivated, as it grows and increases very freely. Like all the snowdrops, these varieties will grow in almost any soil, but if they are to increase properly, they need a deep, rich and well drained situation. The fact that the ground is rather heavily shaded during the summer seems to be an advantage.—BOURNEMOUTH.

PÆONIA MLOKOSIEVITSCHI.

IT may be rash to urge the abandonment of the original botanical name of a plant, but I am confident that he who would give us a better title for such a good peony as this, would deserve the thanks of generations of flower-lovers. No plant, however charming, can hope to become truly popular if cumbered with such an unpronounceable and almost unwriteable name as Mlokosievitschi. Even

Digitized by Google

the fact that it is the best of the true yellow-flowered Pæonias will hardly enable it to overcome the obstacle raised by its specific name. Cannot our Kew authorities step in and come to our rescue? For the plant itself is a handsome and a good one. P. lutea is a poor thing in many ways, although some of its hybrids from France are better, but not so good as this Caucasian beauty. P. Wittmanniana is exquisite, but paler, and has not the reputation of flowering well in many places. But this one is a truly charming border Pæonia, about 2ft. high, with good deep green leaves and remarkably beautiful flowers resembling somewhat those of a water lily and of a hue described by some as citron yellow, but without the tinge of green we usually associate with the expression. It is an excellent grower in an ordinary border and a great acquisition for those who can appreciate single pæonia species with good habit and lovely flowers. Sir Herbert Maxwell grows it well at Monreith.—S. A.

BERBERIS BREVIPANICULATA.

THE various forms of berberis constitute a group of charming shrubs, which ought to be represented in every garden, especially by the fine berry-bearing species, and B. Wilsonæ and the subject of this note may be cited as examples.

B. brevipaniculata is a native of western China, from whence it was introduced by Mr. E. H. Wilson in 1904. It makes a spreading bush of vigorous habit, and it produces a large number of thin shoots or branches, which are eventually clothed with terra-cotta egg-shaped fruits, which are at their best from September onwards. No doubt this barberry would thrive in varied positions, but here at Castleford it is planted so that its lower growths fall over a large rock, where it is very effective in the autumn, while the berries are most conspicuous, being brought more or less level with the eye.

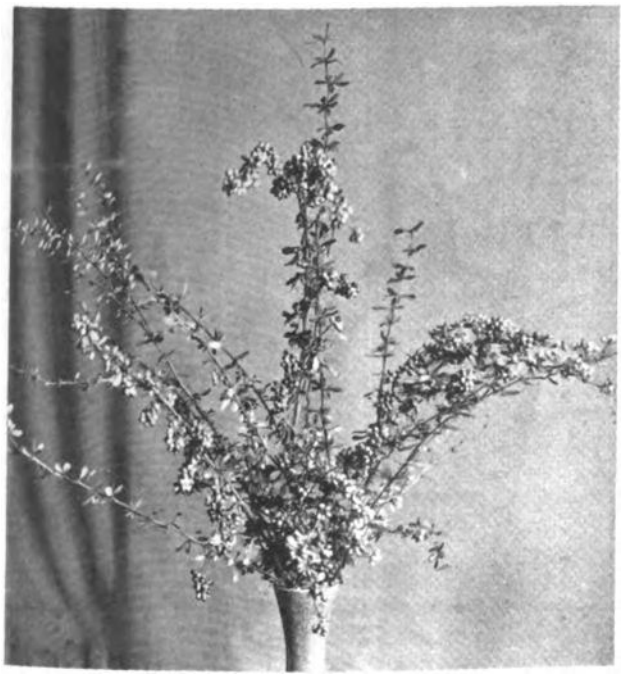
I have heard that some of the berberis do not fruit so freely in certain gardens as they ought to, but the cause, I think, will be found in the soil, which is often too rich. The finest fruiting specimens of B. Wilsonæ I have ever seen were in Mr. H. A. Tipping's garden at Mounton, Chepstow, where they were planted on a bank, and the rooting medium was anything but ideal for the majority of plants. The illustration gives the reader some idea of the fruiting qualities of this delightful barberry.—T. W. BRISCOE.

BERBERIS SEEDLINGS.

WHERE several species of the barberry family are grown in close proximity to each other, there is always the possibility of seedlings appearing which may prove to be hybrids worthy of perpetuating as ornaments of the garden. The great majority will be no advance on already existing species and hybrids, but they are useful for planting in the hedgerow near the garden. A few will appear which are acquisitions to the genus, and these must be propagated by means of cuttings, as they rarely come true from seeds. Having secured what the raiser thinks is a "good thing," I do not advocate giving it a name until it has been tested and compared with other named hybrids, because I think the genus as a whole has already been overdone in this direction.

Personally I am always on the look-out for stray seedlings, especially those that show the slightest departure from the plant which apparently bore the seed, and in the illustration is a barberry seedling with coral red fruits, which is well worth a place in any garden. It is evidently a hybrid from B. Wilsonæ.

The object of this note and photograph is to draw the attention of garden lovers to be always on the watch for self-sown seedlings. There must be many destroyed thoughtlessly, which may have proved a valuable hybrid, or an improvement on the parent. I believe the Apple Cox's Orange Pippin was a chance seedling, also the charming little alpine harebell, Campanula kewensis. No doubt readers could add numerous others.—T. W. B.



FRUITING SPRAYS OF BERBERIS BREVIPANICULATA.

A WELL-FRUITED BRANCH OF A SEEDLING BERBERIS.

POTENTILLAS FOR THE ROCK GARDEN.

ONE of the most useful genera that can be utilised for the rock garden is the potentilla. There are many species, but the ones I propose to deal with here are all easily obtainable from leading nurserymen, and so entrancing and varied that one would think they would be more universally grown.

They all revel in a warm sunny position; for preference, on a light-natured soil. By growing some half-dozen species one can have them in bloom from early May till late September. P. alba is the first to flower, throwing its pretty little white flowers early in May and June. At first sight it is not unlike a strawberry plant in appearance, but the leaves are very much smaller, and the whole is not more than 6ins. high. The next to flower that is worthy of note is P. ambigua. This species forms a dense green carpet, from which in June, spring myriads of large golden flowers.

Following this, we have one of the most beautiful of cinquefoils, namely, P. formosa. This charming plant has a particularly neat habit and is 18ins. high. From June till September it gives us a plentiful supply of blossoms of a bright cherry red colour.

P. Gibson's Scarlet and P. Miss Willmott are two very well known plants. They are both 18ins. high, and look very well when planted on the higher parts of the rockery. On no account plant them in close proximity, as, although very beautiful apart, the colours clash horribly together. The former is of a vivid scarlet colour, the latter a bright rosy carmine. They both flower throughout the summer, and one plant will bear literally hundreds of blossoms.

P. Hopwoodiana is one of the most distinct species. It flowers from June till late August, with blossoms of a beautiful salmon apricot colour having faint white markings. It grows to a height of 18ins., and, incidentally, has had a first-class certificate.

The last of the potentillas to flower is P. Tonguei. It is, in my opinion, the most beautiful of all. The flowers are of a delicious apricot orange, with a blotchy crimson eye. The plant creeps about, and will cover a large area in a season or so. This charming alpine cinquefoil is of hybrid origin and, unfortunately, is not so floriferous as the others; but nothing gives more delight than to see this plant growing on some dry bank or rock wall, exhibiting its flowers of such unusual colouring in September, when there is little else to be seen in the rock garden.—J. BIRKENTALL.

LILIES IN THE GARDEN

SO much interest is being taken in the cultivation of lilies by amateur gardeners, that an account of some of the successes and failures in my small collection may appeal to other lily growers. To begin with, let me explain that the soil here is a rich loam, without any lime in it, full of small stones and, consequently, well drained. The climate is mild with a fairly heavy annual rainfall; the garden is well sheltered from cold winds. Slugs are our worst enemies so far as lilies are concerned, in spite of constant war being waged against them. They gnaw through the lily stems when only a few inches above the ground and attack the bulbs of the smaller and more delicate species below ground. Field mice and voles are present, but the owls keep them well under control and I cannot say I have known them injure any lilies except one bulb of L. rubellum.

Prior to 1919 I had not attempted any lily other than the Madonna, the Martagon and the tiger, but fired by the descriptions of the choicer species in Mr. Grove's invaluable little book on lilies, I determined to see if I could not induce some of them to grow in my own garden. Naturally, L. auratum (The Queen of Lilies) was one of the first to be attempted, but as I had read so much about the difficulty of establishing the typical form, I bought only one bulb. Following Mr. Grove's advice this was planted deeply in a sheltered border between flowering shrubs with plenty of peat mixed with the loam. The result has been very encouraging, for that original bulb has now increased to a fair sized clump and sends up eight or ten stems 7ft. high, laden with dozens of deliciously scented flowers throughout August. L. auratum platyphyllum is usually considered superior to the type in every way and to be much more easily established. Although I have a few very fine plants of this variety (or is it really a distinct species?), I do not find that they increase, and are apt to die out after two or three seasons. The second season after planting is generally the best and a towering stem, 10ft. high, with between twenty and thirty great flowers is certainly a magnificent sight. At the same time it is a troublesome subject to stake, a necessary evil owing to the great weight of the head. Apparently no English nurseryman offers home-grown bulbs of any of the auratum lilies, consequently one has to rely on imported Japanese bulbs. This year two of my platyphyllums have ripened seeds from which I hope to raise young plants in due course. There is a superb crimson-banded form of auratum called rubro-vittatum, but it bears a bad reputation and is high priced.

L. Batemanniæ is generally recommended in catalogues as an easy and beautiful species, but in my experience it is anything but easy and my bulbs (both home-grown and imported from Japan), have so far always collapsed after making a weakly shoot about a foot high. I have tried planting them in leaf-mould and peat and sand and even set them upon inverted flower pots to assist drainage, but after one season's feeble effort they have been seen no more. Mr. Wilson considers this lily to be a form of L. davuricum venustum, not a species. Two hybrid lilies of American origin, L. Burbankii and L. Parda-boldtii, were planted in November, 1924, in a tub sunk in the ground and filled with peat, sand and loam, the surface carpeted with dwarf mimulus and parochetus; they both flowered satisfactorily in the past summer and gave promise of settling down and being permanent residents. L. chalcedonicum maculatum, planted four years ago, has flowered well each season, the sealing-wax red Turks' caps forming a striking bit of colour in front of a group of philadelphus hybrids. This lily has only occasionally seeded here, but it increases slowly at the root.

A GARDEN GROUP OF THE HANDSOME L. REGALE.

The familiar Madonna lily (L. candidum), does only moderately well in this garden, and all too frequently the ravages of Botrytis denude the stem of foliage. Although it is a marvellously tolerant plant, it certainly appreciates a rich soil in an open position, where hungry tree roots do not rob the bulbs of their share of the nourishment. I find it has little objection to being transplanted—at the proper season, of course — just after flowering, and certainly does not respond to the usually recommended policy of "let alone and let it go hungry." The popularity of this old-time favourite is being seriously challenged by the comparatively recent comer, L. regale, and in the not too distant future I think that the Oriental plant will be equally familiar in English gardens. Were I to be obliged to grow only one species of lily, that one would assuredly be L. regale. All flower lovers owe Mr. Wilson a deep debt of gratitude for this splendid introduction of his from western China, not only is it one of the most beautiful and easily grown of all lilies, but the ease with which it is raised from seed has opened the eyes of gardeners to the welcome fact that lilies in general may be grown from seed and that the operation is not surrounded by any mysterious rites, as was popularly supposed. L. regale appears to grow equally freely whether lime is present in or absent from the soil; recent writers are inclined to assert that it requires lime, but I am convinced that this is far from the case. My own home-raised seedlings, about fifty in number, were planted in beds between hydrangeas and azaleas, in which a quantity of peat had been incorporated and which receive an annual mulch of peat. The bulbs appear to appreciate this treatment thoroughly, and send up very vigorous stems with many blooms on each of them; they seed abundantly and some of their offspring now flourish in gardens in New Zealand, the United States and South Africa. L. candidum objects to being given a peaty home, at any rate in this garden. A few bulbs were planted among the regale seedlings, but they have never done

Digitized by Google

so well as those in an ordinary border. L. Henryi is an easy doer in most places and is making itself quite at home here among low-growing shrubs; the 7ft. stems with branching heads are at their best in August. This year a good quantity of seeds ripened on most of the plants of this splendid lily, which should certainly be grown in many more gardens than it is at present. L. speciosum in different varieties has been rather disappointing here so far. Many of the bulbs have failed to put in an appearance after the first season, but a few have become established and flower well each autumn. They are so beautiful and bloom so late in the year, that it is worth planting a few bulbs annually even if one cannot expect to establish it permanently. The two exquisite pink trumpet lilies (L. rubellum and L. japonicum (=Krameri) seem to be very difficult to keep going for more than a year or two in English gardens. We are advised to raise seedlings—luckily

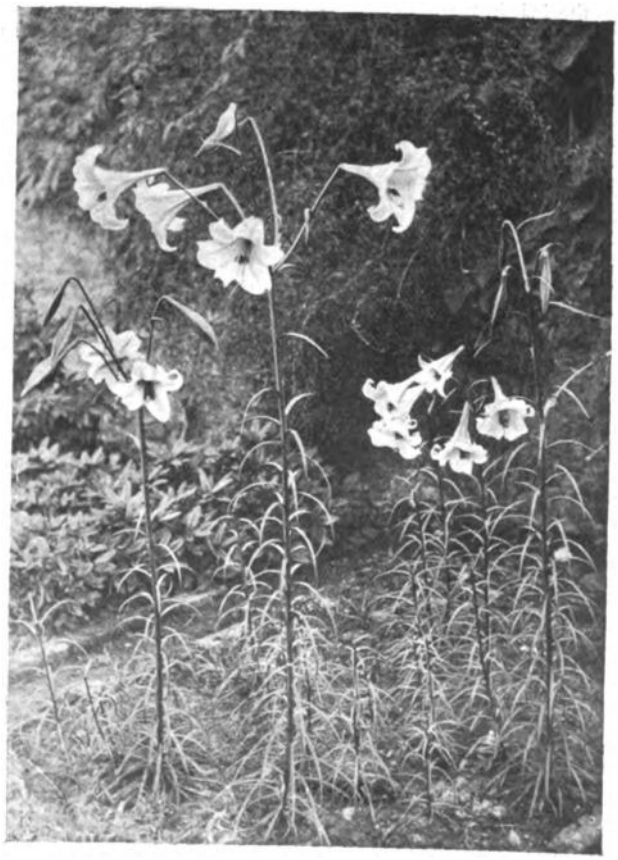
STATELY LILIES IN A PICTURESQUE OPEN SETTING UNDER ARCHES OF CLIMBING ROSES.

The pink and the white are extremely effective in such an arrangement.

both seed freely—but I cannot say my efforts in that direction have been encouraging so far. Slugs are terribly keen on raiding the seedlings and will scale perforated zinc barriers in their greed. Mice, too, are partial to the delicate bulbs, so the owner of a flourishing colony of either of these lilies may well be proud of his triumph. The patches of L. rubellum in the wood at Wisley are sufficient to whet the ardour of any gardener who aspires to grow something worth growing. L. philippinense formosanum (Price's variety), is a very welcome addition to those species which are easily raised from seed and flower in their second or third year. Although quite a dwarf lily in its native habitat, it will reach a height of 4ft. in a congenial position in a lowland garden. It evidently requires very good drainage—some of my bulbs rotted in the excessive wet of last winter—and a cool, peaty soil in half shade. Seed is freely produced, so we may hope to see this very

A CLUMP OF THE NANKEEN LILY (L. TESTACEUM)

desirable lily grown much more frequently. L. testaceum, the Nankeen lily, is an old favourite in many gardens, but nowadays it is a high-priced bulb and few gardeners can indulge in big groups of it. Fortunately it is one of the most easily grown lilies and when established sends up noble 7ft. stems which tower above the small shrubs and



THE TALL AND ELEGANT LILIUM PHILIPPINENSE

Digitized by Google

herbaceous plants in July. Although it is considered to be of hybrid origin, it possesses all the character of a true species.

The numerous garden-raised varieties of L. elegans (Thunbergianum) make a fine show of colour in ordinary soil in June, but none of them appeals to me so strongly as the European orange lily (L. croceum). It is not easy to obtain the true plant from nurserymen, so I was particularly pleased to find some small bulbs growing on an overhanging bank in the neighbourhood of the famous Boréon cascade in the Maritime Alps. They travelled home safely and last June flowered nobly, great chalices of a deep golden hue.

L. Hansoni is one of the élite of the Turks' cap group, a strong-growing, easily managed Japanese. I have never succeeded in getting it to set seed, either when selfed or crossed with others of the Martagon set. It has, of course, been largely used as a pollen parent with the Martagons in the evolution of some beautiful hybrid lilies. Typical L. Martagon is a good-natured plant, but worthy of a place in a choice border among low-growing plants, which will keep its roots cool. Its love of moisture was impressed on me when I found it growing in vast profusion in a wet copse with Herb Paris, Solomon's seal and Marsh marigolds in Dauphiny. A few bulbs were carefully lifted, their stems cut off (though just coming into bloom) and brought home; in spite of this drastic treatment they all survived and have flowered two years later. The white variety is a lovely plant and just as easy to satisfy in the garden. L. pyrenaicum is probably the least popular of the genus and until this past year I could not muster any admiration for the plant. However, an expedition to a locality in North Devon where the Pyrenean lily is completely naturalised in a hedgerow among foxgloves and campions, has converted me to the undoubted charm of the plant when grown in a natural manner. Nothing can be done to conceal the fact that it *is* an evil-smelling lily and it is better to admire it at a safe distance. Probably this is one reason why it is seldom picked and the flowers are thus permitted to ripen seed and spread over a wider area. An unpleasant smell also belongs to the brilliant orange scarlet L. pomponium, perhaps the most strikingly beautiful European lily. It has become rare in English gardens, but as it occurs in profusion in the Maritime Alps and is quite amenable to cultivation in well drained soil with lime in it, it should find a home in many gardens where it is still unknown. My small collected bulbs have settled down well and send up splendid flowering stems much taller than any I saw on the parched hillsides of its native haunts. It is a variable species, like most lilies, and some districts produce superior forms to others. Of several varieties of the tiger lily which I have tried, L. tigrinum Fortunei has proved quite the finest, but the bulbs do not seem to be long lived. The Californian L. pardalinum enjoys our humid atmosphere and has made a brave show ever since the bulbs were planted deep in rich peaty loam in a half-shady position, with Lady Alice Fitzwilliam rhododendrons veiling the lower third of their stems. They were originally planted in a herbaceous border in rather heavy loam and there they would certainly have perished had they not been rescued after a couple of seasons of weak growth. L. Szovitzianum has not been long planted, but judging by the vigorous growth and heads of three or four flowers this past season, it seems to be satisfied with its quarters in the rhododendron bed, in spite of the fact that it is said to be a lime-loving lily. Near by it some young bulbs of the elegant L. Willmottiæ have been planted, one of which has already flowered and shown what a desirable acquisition this fine species must be when really established; it is a much taller and more refined plant than L. Davidii—or L. pseudo-tigrinum, as it is usually named. This last lily has a good reputation as an easy doer, but I have not been very successful hitherto with it; possibly it requires more sun than my bulbs receive in the rhododendron bed.

N. G. HADDEN.

THE FIRST SHOW OF THE YEAR

JANUARY 12th last saw the opening show of the Royal Horticultural Society at the hall in Vincent Square, Westminster, and the bright and varied display staged certainly augurs well for the success and interest of these fortnightly exhibitions throughout the year. There was a certain life in the atmosphere which most of the exhibits themselves seemed to have caught, and in consequence they appeared bright and attractive. Again, the turn of the year induces the onlooker to regard things from a new angle. The Old Year has gone, and with it that feeling of *ennui*, and all one's ideas and hopes are centred on what the present year is likely to bring forth in the garden. The snowdrops and the early-flowering irises bring with them a fragrant whiff of spring; while the flowering twigs of the witch hazels, which have been wonderful this year from a floral point of view, seem to indicate that we may look forward to a very fine flowering season in the world of shrubs. The exhibits were of a miscellaneous nature. Floral groups were to be found mingled with fruit and vegetable exhibits; while those devoted to garden sundries were largely predominant. Undoubtedly each and all contributed to make the first show of the year one which should form a good starting-off point for those to follow. And it is to be hoped that the support which has been given in past years by the public will be maintained during this one.

The three leading carnation firms had their customary exhibits. Messrs. Stuart Low and Co. staged some fine blooms, together with a collection of orchids, a few cyclamen and other greenhouse plants. Some of their best carnations were Sir Philip Sassoon, one of the finest crimsons; Master Michael Stoop, a glowing cerise; Sheila Greer, orange flecked flame scarlet; and Lady Hindlip. The latter variety is an attractive, well shaped carnation of medium size; colour white pencilled heavily with red.

Mr. C. Engelmann also exhibited a collection of perpetual-flowering carnations, and among them Red Laddie was a flower of great substance; and Betty Lou, a pretty rose pink; Doris Cox, a new variety shown by this grower, is of a somewhat poor colour—it contains too much of the bluish tinge which spoils so many of the pinks and magentas.

The long period over which both the perpetual border carnation and the Allwoodii can be had in flower is proved time and again by Messrs. Allwood Brothers, for at nearly every show throughout the year they stage collections of these flowers. At this show they exhibited such Allwoodiis as Betty, Phœbe and Beatrice; the perpetual border carnations, Sussex Flake and Sussex Ray, together with Cameron, Beauty of Durham, Shot Silk, and Chintz, and many other good perpetuals.

A most imposing group of that fine Christmas-flowering greenhouse plant, Poinsettia pulcherrima, was arranged by the Hon. Vicary Gibbs. A few perfect and very fragrant roses were shown by Mr. C. Engelmann, and among them Columbia, Premier and Souvenir de Claudius Pernet were noticeable. Messrs. R. Gill and Son staged a group of Christmas roses and poppy anemones in all shades. Messrs. Bunyard exhibited a collection of apples in excellent condition. Such apples as Mére de Ménage, Coronation, Peasgood Nonsuch, Lord Hindlip, Wealthy and Tibbet's Pearmain were brilliantly coloured and of good size. A small group of chrysanthemums was arranged by Messrs. Cragg, Harrison and Cragg.

A really magnificent collection of vegetables was set up by Messrs. Sutton and Sons. Their skill not only as raisers and growers but as exhibitors as well was fully evidenced by this group. Vegetables of all kinds, both common and uncommon, were included. Chicory, dandelion, scorzonera, celeriac, endive, salad potato, mushrooms, as well as many varieties of carrots, parsnips, onions, beet, etc., were on show. Very large specimens of the onion Sutton's Selected Ailsa Craig and the leek Sutton's Royal Favourite were displayed.

The first spring flowers of the year were shown in informal rock gardens, in which they look remarkably well, for, although they are not especially adapted to live among rocks, many of our earliest hardy plants happen to have their home in stony places and with the turn of the year the garden is brightened with many bulbs which are accustomed to rush into flower before the fierce sun of early summer burns up the stony soil of the eastern Mediterranean and Asia Minor.

Messrs. Waterer showed Iris Sind-pers, which retains most of the strange colouring—sea green and pale blue—of its parent, I. persica and, although it is much less subtle and distinguished, is more vigorous and easier to grow. I reticulata and a good form of I. stylosa (which seems naturally reluctant to reassume its ugly, but proper name, unguicularis, which the learned have prescribed for it); that beautiful, but neglected sisyrinchium, S. grandiflora, with its ample, swinging bells of purple and a very happy association of dull, brownish pink heathers and pale blue muscari.

Mr. F. G. Wood showed Crocus Susianus, C. Sieberi and Primula Juliana, very bright and gay against some dwarf retinosporas, in their winter dress of purplish brown; double primroses and Christmas roses were grouped at the foot of a fine specimen of Viburnum fragrans, which was covered with its pearly pink flowers.

Messrs. Cutbush relied for colour chiefly on the waxy pink berries of some good forms of Pernettya mucronata and some varieties of Erica carnea against a background of dwarf conifers and a carpet of silver saxifrages.

The chief feature among the orchids was the wonderful group of Cypripedium hybrids

Digitized by Google

shown by Mr. G. F. Moore, V.M.H., Chardwar, Bourton-on-the-Water, Gloucestershire. Of the 200 plants staged, all but six were raised in this amateur's collection. This group was generally considered as the finest lot of cypripediums ever shown at a meeting of the Royal Horticultural Society. Colour and size were prominent, and all the plants were in vigorous condition. When it is stated that C. chrysostum measured 4½ins. across the dorsal sepal, some idea may be gained of the immense size of these grand hybrids.

Another fine group was that shown by Mr. Robert Paterson, Cathcart, Glasgow, and to which a gold medal was also given. It contained a representative selection of the popular genera, mostly hybrids and proved the great utility of orchids as winter-flowering plants. The fact that this group had been brought all the way from Glasgow added much to its merit and interest.

Mr. H. T. Pitt, Rosslyn, Stamford Hill, had a very interesting group of species and hybrids, among the former being Cattleya chocoensis alba and Odontoglossum Uro-Skinneri album, while the latter included Cypripedium Forest King and a cluster of the little Epidendrum Endresio-Wallisii.

Messrs. Sanders staged an attractive group in which the central plant was Cattleya Tityus, with a spike of three rose-coloured flowers. On each side were large plants of Cymbidium hybrids, various cypripediums and in front one noticed several rare species.

Messrs. Charlesworth and Co., Haywards Heath, put up a pleasing exhibit in which some new odontonias were in prominent places. Several odontiodas were noteworthy on account of their intense reddish colour.

Messrs. Stuart Low and Co., Jarvisbrook, Sussex, exhibited several meritorious plants in their group, the best being Cymbidium Atalanta, with a tall spike of many flowers and Sophro-Cattleya Doris, with flowers of reddish scarlet colour. Among the species were Epidendrum vitellinum, with neatly formed flowers of orange-red, and Masdevallia ignea, of fiery red colour.

Messrs. Cypher and Sons showed a number of choice cypripediums, the pretty Calanthe Harrisii, with white flowers, varieties of Lælia anceps, and well flowered plants of Masdevallia tovarensis, as well as odontoglossum hybrids and odontiodas.

Various cypripediums, of which Leeanum and Olympus may be given as the best, were staged by Messrs. J. and A. McBean. Also odontoglossum hybrids and a form of Cymbidium rosefieldense, with greenish flowers.

Messrs. Armstrong and Brown, Tunbridge Wells, arranged a pleasing exhibit of cypripedium hybrids and various odontoglossums. In the centre was Lælio-Cattleya Schrœderæ with a spike of six flowers, white, except for the purple lip, while at the back was Odontoglossum harvengtense.

Messrs. Cowan and Co., Southgate, had an interesting group of cypripediums and cymbidiums, the former including Vashti and Golden Wren, the latter Atlas and Goldflake. A very fine variety of Miltonia Bleuana was staged, also Odontoglossum Robin Hood, with flowers of claret-red.

Messrs. Black and Flory, Slough, staged several elegant cypripedium hybrids, of which Golden Wren deserves mention; also Cattleya Lysander, of pleasing coloration; Sophro-Lælio-Cattleya Vulcan, of rich purple; and Potinara Royal Purple, the latter combining the four genera-brassavola, lælia, cattleya, and sophronitis.

The largest and most comprehensive collection of garden tools and sundries was set up by Messrs. Wood and Sons. On their stand every kind of garden implement could be seen. Spraying machines, fertilisers, baskets, insecticides, mats, secateurs, twine, forks, spades and many very useful appliances were exhibited. Messrs. T. Gunn and Son also showed garden tools, lawn mowers and sundries of all kinds. Messrs. C. Pugh and Co. demonstrated the Atco motor mower. Messrs. Sander and Co. showed a number of bird baths, sundials and garden ornaments of good design to suit all types of gardens. Labels were exhibited by Messrs. J. Pinches and Messrs. Carter and Williams. The Chase Continuous Cloche Company showed alpine plant protectors; Mrs. A. Everitt, gardening gloves; The House and Garden Supply Company, plant supports and sundries; Mr. C. Jardine, secateurs and pruning knives; and Mr. Wood, Willmott plant supports.

AN ORNAMENTAL GREENHOUSE SUBJECT, DOMBEYA GLANELIÆ.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

DOMBEYA GLANELIÆ.—This is a representative of a genus which is little known in this country, although why it is should be so is difficult of explanation. The majority of the species are ornamental subjects for the cool greenhouse and are very showy with their heads of rosy or white flowers, either loose or clustered, and their handsome cordate foliage. This species bears dense heads of rose pink flowers which hang down gracefully on a long stalk. Unfortunately, they are rather hidden by the large heart-shaped leaves, which are from 9ins. to 1ft. across. It would appear to be closely allied to D. Wallichii, and is an exceedingly showy subject when in bloom. It is unfortunate that the true specific name of this plant was not given, as the coining of new specific names makes confusion worse confounded. Shown by Lord Glanely (gardener, Mr. Bannerman), Chippenham, Wilts.

CHRYSANTHEMUM WINTON.—Fine upstanding medium sized blooms of a good yellow colour. The florets are firm and lend some character to the flower which is well carried on long stout stems and is shown off to advantage by the brightly polished, almost varnished-looking, foliage. Shown by Messrs. Tacon and Horwood, Cheshunt.

ORCHIDS.

FIRST-CLASS CERTIFICATES.

CYPRIPEDIUM MARMION, HOLFORD'S VAR. (Germaine Opoix × Jura).—This elegant hybrid bore a large flower having the dorsal sepal almost covered with crimson suffusion except the white apical border; the petals are broadly developed, yellowish, heavily stained with mahogany red; the labellum equally well developed and similarly coloured. Shown by Lieut.-Colonel Sir George Holford.

CYPRIPEDIUM CHRISTMAS CHEER.—Parentage unrecorded, but one of the most attractive of flowers, both as regards formation and colour. The dorsal sepal is mainly dark purple, the upper part being white. The petals are undulated on the margin, of mahogany red colour, with darker venation, and bordered with yellow. The labellum stands out prominently on account of its form and rich reddish crimson colour. Shown by Mr. Robert Paterson, Cathcart, Glasgow.

BRASSO-CATTLEYA MRS. ROBERT PATERSON (Cattleya Clotho × Brasso-Cattleya Cliftonii).—This pleasing flower has the segments of model formation, the petals of thick texture and almost meeting one another in front of the upper sepal. In colour it is bright mauve-pink, the front of the labellum crimson, with a narrow mauve border, slightly crisped, and the throat yellowish. Shown by Messrs. Black and Flory, Slough.

AWARDS OF MERIT.

CYPRIPEDIUM BALDUR, HOLFORD'S VAR (G. F. Moore × Niobe).—This hybrid muc. resembles the well known Niobe type. heh dorsal sepal is prettily stained and marked with rose-crimson, the petals and labellum reddish brown. Shown by Lieut.-Colonel Sir George Holford, K.C.V.O.

CYPRIPEDIUM SALADIN (Chapmanii × Olenus).—The chief attraction in the flower lies in the large and broad petals, which show the influence of Cypripedium bellatulum, contained in both parents; these petals are thickly covered with small spots of intense red colour. The dorsal sepal is comparatively insignificant.

CYPRIPEDIUM ST. KENTIGERN (Albert Fisher × Perseus).—Although somewhat poor in

Digitized by Google

formation, this hybrid is unusually well coloured. The dorsal sepal of intense crimson, bordered with white, the petals mahogany red, the labellum reddish with a yellowish margin.

MILTONIA PRINCESS MARY, VAR. ROSEUM (Hyeana × Bleuana).—This popular hybrid bore an arching spike of five flowers of bright rose colour evenly displayed throughout all the segments; the labellum bears a mask-like blotch of deeper colour at its base. The above three were shown by Mr. Robert Paterson, Cathcart, Glasgow.

CYMBIDIUM ERIN, GATTON PARK VAR. (grandiflorum × gattonense).—A beautiful hybrid which bore a spike of eight large flowers of clear green colour in the sepals and petals, the labellum yellowish with red spotting and a median line of similar colour. The flowers are strongly scented. Shown by Sir Jeremiah Colman, Bt., Gatton Park, Surrey.

PLUMS AND CHERRIES

SOIL.

PLUMS, with which are classed gages and damsons, will succeed in a variety of soils. The ideal would probably be a good deep loam which is neither too dry nor has a wet subsoil. Subsoils of gravel or chalk are secure against the latter condition. It is not, however, unusual to find excellent standard trees bearing heavy crops growing in soils where the subsoil is clay. The main point in such a case is, before planting, to ensure perfect drainage, especially if it is intended to grow dwarf or trained trees.

Plum trees are generally budded, or occasionally grafted, on to one of the various plum stocks. A few varieties are grown on their own roots, and are mostly popular in particular localities, such as the Pershore plum in Worcestershire. Whether budded on to one of the many common stocks or grown on its own roots, the root system is inclined to be strong. By several transplantings of the trees during the first five or six years, and by an equal number of shortenings back of strong roots, a fine fibrous root system is developed. As there is no very dwarfing stock for the plum or cherry in the same degree as is found for the apple and pear, by the Paradise and quince stock respectively, it is essential to encourage this fine fibrous root system, especially for bush or trained trees, before they can be brought into proper bearing.

Having obtained this desirable root system, it will readily be understood that extreme changes of moisture and dryness are prejudicial to their well-being. One of the best safeguards against this is to prepare the soil well by deep digging, and if necessary to provide drainage of some sort; broken bricks are excellent for the purpose. This applies generally to all stone fruit.

Unless the soil be very poor, no farmyard manure ought to be necessary at the time of planting. A rich soil would tend to excessive growth in the early stages, and while a sufficiency of healthy shoots is necessary to build up the tree to fruiting size and age quickly, the difficulty often is to control growth. A sprinkling of bone-meal and wood ashes at the time of planting is beneficial, and, above all, lime in some form is essential. Old lime rubble is excellent. Most soils contain a supply of lime in varying quantities, and it is well known that stone fruits do best in soils containing the latter in considerable quantity. This point should always be borne in mind and remembered, that stone fruits make a considerable demand upon the available lime in the soil. Heavy cropping combined with natural causes of exhaustion may reduce the available lime to a minimum. In such cases it must be replaced by a dressing in early spring.

SITUATION.

The plum tree is perfectly hardy, but as it blossoms early the flowers are always more or less at the mercy of spring frosts in addition to inclement climatic conditions generally. The sheltered garden has, therefore, an advantage over trees planted in exposed positions, and trained trees on walls have an additional advantage, inasmuch as the wall is often sufficient to safeguard the flowers against slight frost and the trees can, if necessary, be protected by means of fish netting or other slight coverings.

FORMS OF TREES.

Undoubtedly the easiest form of tree to manage is the standard, as, after it has once got into bearing, very little pruning is necessary, the balance of the tree being maintained by proper cultivation and manuring according to the annual crop of fruit obtained. This type of tree is not always a convenient one for private gardens, especially the smaller ones. However, the plum tree lends itself to training into various shapes, and of these the bush form is generally grown in the open where space is limited. Even this, if allowed to develop, will often make heads quite as large as the standard, owing, no doubt, to the same stock being used for the bush as for the standard. Of the many stocks used, perhaps the St. Julien would have a slight tendency to dwarfing the tree worked on it. This stock, in its natural state, is certainly a dwarfer growing tree than most of those which are used for stock purposes.

The fan-trained tree is suitable for walls or fences with any aspect except north, and even for this it is sometimes utilised. Only dessert varieties would, of course, be given the favourable position of a wall. When plums and cherries are grown, the latter should be given the east wall in preference to the west, owing to a likelihood of storms coming from the west, which, in some seasons and localities, tend to crack the ripening fruits.

PLANTING.

Trees which have received proper attention in the nursery should be chosen. By that is meant the initial training of the trees into whatever shape it is intended to make them, and annual transplanting and shortening of strong roots to develop the desired fibrous root system. Although autumn is acknowledged to be a good time for planting fruit trees, it can, however, be safely done at any time during winter or when the trees are dormant, providing the soil is in a suitable condition.

Care in planting is important. The roots should be examined, and any damaged ones shortened with a clean upward-slanting cut, afterwards spreading them all out in their horizontal positions. If dry at the time of planting, it will be distinctly advantageous to soak them in water before planting.

In the planting of all trees a little special attention is well repaid. A sprinkling of fine soil over and around the roots will, I am convinced, give them a start over those given less careful treatment. Firm planting is essential, but an inch or so of fine surface soil should be left around the tree when planting is completed. A mulch of long litter around the trees for the winter would be advisable.

TRAINING AND PRUNING.

The principal work before the trees reach bearing age will be to continue the training and do any necessary pruning. This, in the case of plums and cherries, will be much in the nature of summer pruning. The plum fruits on spurs or one or two year old wood. The bush form must be trained with sufficient leading shoots to form the framework of the tree, usually six to eight, and on these, spurs should be encouraged by the summer pinching of lateral growths. If this be done early it will help to this end. In the case of fruiting trees it will allow the sap to be drafted into the swelling and ripening fruits, thus increasing size, colour and flavour.

Summer pruning will also neutralise the danger of gumming, which is often brought about by strong winter pruning. The leading shoots will need a little shortening annually at winter pruning until the tree comes into bearing.

It is often difficult to maintain equality of strength in these young principal branches, and assistance must be given by means of depressing early the overvigorous shoot and elevating the weakest. It is sometimes advisable to check the strongest shoots when about a foot of growth has been made, by pinching out the leader instead of leaving this till winter pruning.

The laterals, which in summer were shortened to five or six leaves, will in winter be further cut back to about three eyes.

The standard may reach fruiting age without any further root disturbance, but the dwarf bush or other trained trees will, in all probability, require lifting and transplanting to throw them into bearing. When doing this any strong roots must be shortened back according to their length and vigour. This treatment is infinitely preferable to root pruning, as the term is generally understood. The work can be done easier and more satisfactorily by lifting than delving under the ball in search of offending tap roots, and if done carefully, the plum is one of the easiest trees to transplant. A. J. COBB.

(To be continued.)

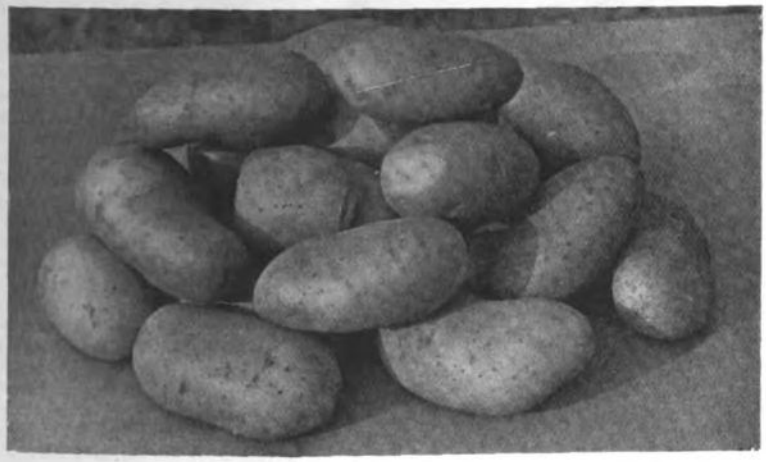
TWELVE GOOD POTATOES

I WAS asked the other day which I considered the twelve best varieties of potato. Well, that is a very difficult question to answer, and from among the hundreds of varieties catalogued it is not a simple matter to choose twelve and say "These are the best." One man may consider my list poor because I have not chosen more exhibition varieties; another may comment on the fact that some are not suitable for his particular soil; while a third will say that I have ignored the newest varieties. However, I intend this list to be one of good varieties of general utility, and am relying mainly on well tried sorts. Of course certain soils produce far larger crops from certain varieties, and one must, to some extent, be guided by local conditions. For instance, Golden Wonder, a favourite main-crop potato in some districts and a really high-class tuber, is of little use except in a good, rich, well worked loam; while Sharpe's Express is far more prolific on a light soil than on a heavy one.



DARGILL EARLY, ONE OF THE BEST EARLY IMMUNE VARIETIES.

Among the early varieties there are several good croppers producing high class tubers, and from this class I choose the following:

MAY QUEEN is the earliest potato I have grown and is suitable for forcing in frames and for earliest use outdoors. The tuber is white and kidney-shaped, but this variety is not a heavy cropper.

MIDLOTHIAN EARLY (DUKE OF YORK) is a variety which may be classed with May Queen, or perhaps it would be more correct to say that it would follow that variety, for it is just a little later. Yellow and kidney-shaped, it is not a heavy cropper, and owes its value, like the preceding variety, to extreme earliness. I do not advocate the planting of large quantities of these two varieties, but a few rows will bring new potatoes to the table early when the price is high and new potatoes are indeed a luxury.

To follow these two varieties we look for a heavier cropping potato, which will mature a week or two later, and for this purpose we have:

EPICURE, a favourite market sort of good quality which is round and white. In spite of it being a quality potato, it is losing favour in gardens owing to its shape, which is often ugly.

SHARPE'S EXPRESS, one of the heaviest cropping early potatoes grown, is a variety which still holds its place, both in gardens and among market growers. It is a white kidney of fine quality, its chief fault being that it should not be lifted until nearly mature, otherwise many of the tubers will be too small to use.

One other early variety I must mention for this reason. All that I have alluded to so far are susceptible to that terrible potato scourge, wart disease, and people living in an area infected with this plague will not be able to plant them. Fortunately, we have some varieties which are immune from this disease, and can be safely planted, no matter how badly the soil is infected.

DARGILL EARLY is one of the best early immune varieties. It is a kidney-shaped potato, rather pale yellow in colour and of good quality.

The second early varieties include some of our heaviest croppers. These varieties are usually lifted just before maturity and are used to fill the gap between the light-cropping earlies and the heavy cropping main and late varieties.

BRITISH QUEEN, a heavy cropping white kidney, is an old favourite with most growers. It is, perhaps, more suitable for growing in the Midlands and the North, as it is so very susceptible to blight, and in the South where blight appears early, the crop often suffers.

GREAT SCOT is, to my mind, the very best second early. A huge cropper, producing good sized clean tubers which are white-fleshed and round in shape. It appears to do well on both heavy and light soils; in fact, during that very dry season three or four years ago, I lifted a larger crop from this variety on a sandy soil than from any of the main-crop varieties. Another point in the favour of Great Scot is the fact that it is immune from wart disease.

THE ALLY is not of such a high quality as Great Scot, but, owing to its capacity as a cropper and the fact that it is immune from wart disease, this kidney-shaped potato should be included.

KING EDWARD.—When dealing with main-crop potatoes I must speak of King Edward first. This potato does not need any describing. I think everyone knows it. Housewives, even in London, know King Edward and ask for it. I think it needs no recommendation. However, it is not the only potato in this class, neither is it the best cropper. It is not immune from wart disease; but K. OF K., which is described as the immune King Edward, is both immune and a good cropper.

KERR'S PINK has in many tests produced the heaviest yields. It is immune from wart disease and also resistant to blight. As its name implies, it has a pink skin and is round in shape, but inclined to be irregular.

MAJESTIC is rather a new variety of good quality and immune from wart disease. A heavy cropper of kidney shape, it is well worth growing.

ARRAN CHIEF, the last potato I am going to mention, is almost as well known now as King Edward. A roundish, rather badly shaped tuber, it is of really good quality and is a great cropper.

Before I close these notes I should like to stress two points. Whenever possible buy Scottish seed, for this undoubtedly gives the best crops; and always deal with a good firm—one with a name to support.

N. D. H.

CORRESPONDENCE

PRIMULA DENTICULATA.

SIR,—In your issue of January 9th, I notice a short article on Primulas which invites comment. Dr. Schneider regrets the absence of P. Littoniana from the gardens of central Europe. There is no reason why this very striking primula should be absent from Continental gardens, as many readers of your journal will agree. It is now by no means rare in English gardens. It is quite hardy and seeds freely. It is a plant of moist meadows and in cultivation must never be allowed to get dry at the root. A stock of young plants must be kept for a succession as it is biennial in our gardens. It is variable in colour and in length of spike, the largest spiked specimens usually being the poorest in colour.

I agree with Dr. Schneider's appreciation of P. denticulata and its forms as garden hybrids. The view that P. cashmiriana is a natural hybrid between P. denticulata and P. capitata is an old suggestion, but it is a very doubtful one. P. denticulata in the Himalaya is a very early primula, where P. capitata is one of the latest. So, too, the grower will find in his garden. Neither are they very closely allied. P. cashmiriana is clearly of near affinity to denticulata and without capitata influence. The grower will find it of advantage to keep the primulas referred to above in three groups—very easily recognised. The true capitata primulas have the flowers in a dense ball-like inflorescence with the flowers pointing mostly downwards and a few empty bracts on the crown. They are all *late* primulas. The denticulata section

Digitized by Google

has a similar inflorescence, but the flowers point upwards and do not droop. They are mostly early flowerers. The muscarioides section to which Littoniana belongs is readily recognised by the flowers being in a dense spike and not in a round head. Their period of flowering is generally between the other two sections.

P. stolonifera collected by both Forrest and Schneider in the Lichiang valley, belongs to the denticulata aggregate. Seeds, no doubt, were secured, but, as far as I know, no plants of it were raised. At any rate, no plant has appeared of this section with the characteristic robust naked stolons of stolonifera. From the garden point of view this may not be a matter of great regret, as the original specimens show a very inconspicuous head of flowers as compared with the forms of denticulata already in cultivation.—W. W. S.

LILIUM AURATUM PLATYPHYLLUM.

SIR,—I am sending you a photograph of a clump of Lilium auratum platyphyllum which was taken in my garden here last summer and which may be of interest to your readers. I obtained the bulbs from Messrs. Barr and Sons, in February, 1920, and I put a few in an azalea bed. They have increased every year and last year we had some splendid lilies. The one by which I am standing measured 7ft. 8ins. Its height will readily be seen by the unopened buds at the top. I prepared the beds for the lilies and planted them, and at the time made a note of the soil, etc., used as I had never grown any platyphyllums before. The natural soil, which is sandy loam over sandstone, was taken out for about 2ft., and old manure mixed with soil put at the bottom, then a layer of peat. The lilies were planted on this about 10ins. deep and surrounded with sand and dusted with sulphur. The hole was then filled in with the turf soil, leaf mould and some bits of charcoal. Every spring I dress the bed with old manure mixed with a little Vaporite, as we are rather plagued with slugs here, and I water them nearly every evening during the summer when the weather is dry and hot. The bulbs must have increased considerably as I only planted five in that clump to begin with. They really were a wonderful sight last summer.—(MRS.) R. BUTLER, *St. Leonards' Park, Horsham.*

THE QUEEN OF LILIES L. AURATUM PLATYPHYLLUM.

LONICERA FRAGRANTISSIMA.

SIR,—I was much interested in the note on Loniceras by Mr. Moore in a recent issue of THE GARDEN.

I should be obliged if he could tell me how to get L. fragrantissima to bloom. I have had a plant now for the past five years and have not seen a bloom, although the wood is well ripened: until last autumn I had it against a wall in a sheltered corner, but moved it then to a more open spot; and yet there is still no sign of flower. Perhaps he can tell me why.—F. W. HARRIS, *Lydney, Glos.*

FLOWER NOMENCLATURE.

SIR,—I am only a rudbeckia. Alas! I too, have a name that is not very English; but, as Horace said long ago, "Nunc est Lucarnendum," and surely, even if my name is Teutonic, it might at least be correctly spelt. One catalogue gives "Herbstone," another "Herbstonne," and there are others who give me all sorts of variations between and betwixt. The crowning insult is "Kerbstone."

Now, *Herbst* means autumn and *Sonne* is sun, and therefore, as I bloom and bloom and bloom all the autumn like the sun in splendour my name is, yours most horticulturally, RUDBECKIA HERBSTSONNE.

ERITRICHIUM NANUM.

SIR,—Your correspondent, Mr. F. Barker, in the issue of December 26th, 1925, asks if any other readers have found any variation in the colour of Eritrichium nanum. During the last four or five summers I have seen it in many places in the Alps, growing in most cases tightly wedged in a chink or crevice of hard, igneous rock and once, on the top of the Mulaz Pass (8,400ft.), in the Dolomites, on limestone rock. In other places in the Dolomites I found it in much greater profusion growing in rotten igneous rock and schist and here the tufts were often less compact and the flowers less dwarf, but in no case was there any variation in colour from the intense blue, which must be seen to be fully realised.—ROY PINSENT, *Birmingham.*

CHRYSANTHEMUM SOURCE D'OR.

SIR,—Early in January I paid a visit to a Scottish garden and while walking round my attention was drawn to the old variety, Source d'Or chrysanthemum then in fine flower, under glass. This variety was so ably described by "Claremont," in THE GARDEN of January 2nd, that to give it further praise would be out of place. This, however, will serve to show that in Scotland at least Source d'Or is still to the fore.

One other old variety which I am sure "Claremont" will know is Sœur Melaine; this pompon has pure white flowers, most useful for table decoration, and very effective when intermixed with sprays of Salvia splendens.

This variety has evidently been known for fifty years. I have grown Sœur Melaine for several years and its constitution in no way seems to deteriorate.—D. A., *Midlothian.*

ORIGIN OF NERINE BOWDENI.

SIR,—In reply to Sir Herbert Maxwell's enquiry (page 733, December 26th, 1925), I obtained the bulbs of Nerine Bowdeni from Mrs. Cornish-Bowden (member of a well known Devonshire family), who informed me that they were collected by her son, Captain Cornish-Bowden in the hills near Grahamstown, South Africa.

I exhibited the plant on October 18th, 1904 (obtaining an A.M. from the R.H.S.), under the name of N. excellens major tardiflora, but this name was changed in 1908 to "Bowdeni," after the collector.—PETER C. M. VEITCH.

NOTES FROM A FAR-OFF ROCK GARDEN.

SIR,—As you have invited notes on gardening matters, perhaps an account of a few of my treasures may prove interesting. Some time ago a correspondent asked if anyone grew Viola cenisia from seed. I grew four plants, three of which I put in the moraine. A slug devoured one, but the others are looking very happy. V. heterophylla, also from seed, is looking extremely cheerful in our moraine. Neither V. cenisia nor this have flowered yet, though I am full of hope. Silene acaulis has made patches of delicious moss-like foliage, and four out of five look like flowering, but after all the dismal things that are said of it, it will not do to be too optimistic. Dianthus glacialis flowered well and contrary to expectations D. sylvestris bloomed freely, and fully deserves all the fine things that are said of it. D. alpinus is also doing well, but I think it is better for more soil than the moraine gives. Various other dianthus have brought me nearer to a mental hospital than I hope to go ever again. I take the list of the seed I bought and try to check up the descriptions of what they ought to be, and what they are. I have the smallest possible dianthus on stems 4ins. high, with perfectly smooth, oval-topped pink petals. I imagine it to be sub-acaulis. Then I have a white one about the size of Silene alpestris. What on earth is this? Its foliage is not more than 1in. high, but its solitary flower stems are six. It is a pet, anyway. I have what I bought for D. gallicus, and I am sure it is D. graniticus, heaps of pink stars, slightly toothed and darker at the points, very floppy foliage 2ft. long, with bronzed stems and joints. I have looked at two plants with wild lace-like blooms and tried to make up my mind which is squarrosus and which superbus, till my head has whirled. One is enormous and heavily perfumed, the other is smaller with greener, finer grass. I have finally decided and am probably wrong, that this is superbus, though the name would fit the big chap better.

Sedum pilosum is a mass of pink flowers. Ranunculus insignis, from the shingle slides of Mt. Ruapehu, is flowering with huge varnished golden blooms as big as a small salt cellar. Only one group of plants refuses to flower with me—the encrusted saxifrages.

Digitized by Google

I have tried all kinds of soil and positions I can think of. The climate is beyond criticism, though, perhaps, wanting in extreme cold in winter. If anyone can make any suggestions I shall be eternally grateful. It seems to me that plants often behave very differently in New Zealand from what they do elsewhere. My best D. neglectus is growing chubbily and full of colour in a strong limey soil. Silene pusilla one sees little mention of in garden notes, yet the late Reginald Farrer said it was "a thing of unimaginable daintiness and charm for any dank corner." — E. O'CALLAGHAN, *Hawera, New Zealand.*

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

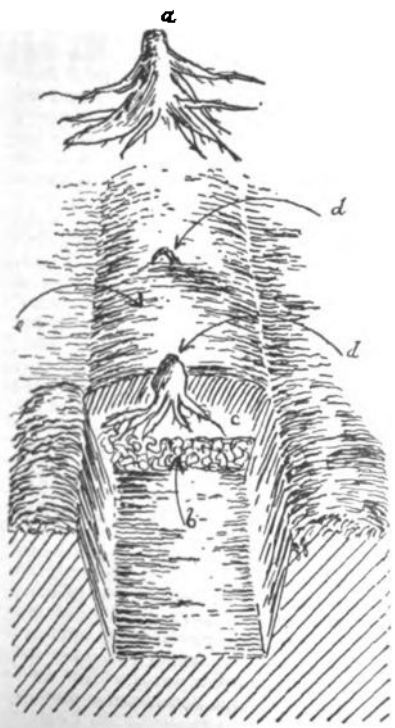
VEGETABLES

CAULIFLOWER WHITE QUEEN.

THOSE on the look out for a cauliflower to produce large, pure white and finely shaped heads, should grow Sutton's White Queen. Last year throughout the month of July we had a very fine crop of this variety. The seed was sown early in September and the seedlings when sufficiently grown were pricked out a few inches apart into cutting boxes filled with medium fine soil, and wintered in a cold frame. About the middle of March the plants—after it was ascertained that they were sufficiently moist at the roots—were carefully raised from the boxes, so that each plant had a good ball of soil adhering to its roots. Then they were set out with a trowel at 1ft. apart in single lines, in good, well tilled soil in a sheltered border, and between the earth ridges, which covered the early potato sets. Everything was done to give the plants as little check as possible in the move from the boxes to the open ground. In this position the plants grew splendidly and produced—in addition to fine white heads—large spreading foliage of a deep blue colour.—D. A.

PLANTING RHUBARB.

RHUBARB may be planted any time from November to March when the weather is open and the soil is in a fairly dry condition. When the cultivator decides to plant rhubarb, he should duly consider whether he wishes it to remain permanently in the position selected, or whether it will in due course be lifted and forced in a forcing pit or some kind of building. If it is to be a permanent crop the soil should be entirely freed of all deep-rooting weeds and this can be easily done when the soil is being trenched as it should be trenched at least 3ft. deep. If the roots are to be lifted the same care should be taken as regards the preparation of the soil, but the roots may be planted a little closer—about 6ins., to economise space. An open quarter, not overshadowed by trees or high buildings, is most beneficial as the crowns should be well matured every year. After planting new crowns, do not pull sticks from them the same year. The letter *a* in the accompanying sketch shows a single crown with thick, strong roots; this is the right kind to plant, whether it be bought or taken from divided clumps at home. Rotted leaves, manure and soil, all mixed, should be placed in the wide trench as shown at *b*, the root *c* being well embedded in good soil, dry and rather fine. The crowns *d*, *d*, are shown just clear of the soil *e*, which is higher than normal level at the time. This is done so that the soil and plants will not sink below normal level when they finally settle down. Three feet apart is a good average distance to plant.—G. GARNER.



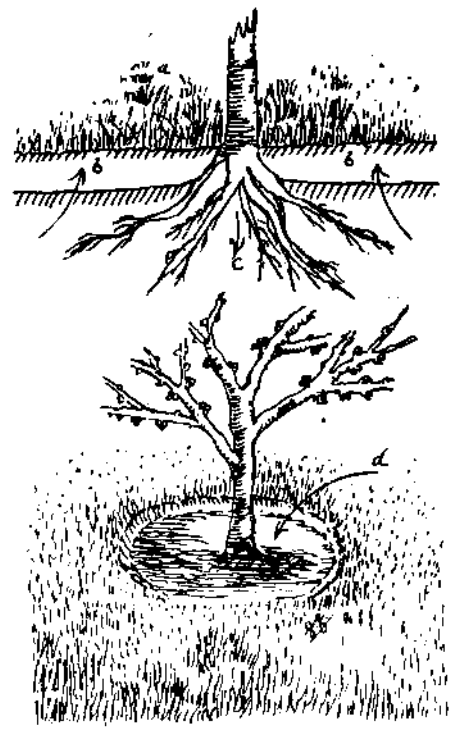
COLEWORTS: HAVE THEY GONE OUT OF FAVOUR?

IN every large establishment it used to be the practice when sowing, in spring, cabbage and other members of the brassica family, to include coleworts, so that, in early winter and, indeed, as an autumn crop, following beans and late peas, a breadth of this delicious vegetable was ensured. So far as my observation goes, and from enquiries made, this once-recognised rule is honoured now more in the breach than in the observance. In the gardens of amateurs it was never very popular, and one would not be wrong in saying that, like Portugal cabbage (Couve Tronchuda), coleworts are scarcely known. But they deserve a place in every garden where a vegetable of a very agreeable flavour is appreciated, as they come in as a change from the earliest of winter greens. For small gardens, too, where space is a consideration, coleworts are worth attention and it has always been to me a matter of surprise that they have been left in the lurch. It is somewhat curious, too, that in provincial markets one seldom meets with them offered for sale, and to ask for them generally elicits the well worn reply, "We have no call for them," the truth being that the ordinary householder has never had the opportunity of purchasing a supply.—CLAREMONT.

MISCELLANEOUS

GRASS, OR NOT ANY GRASS, AROUND FRUIT TREES.

DURING the past few years I have noticed several orchards in which grass has been allowed to grow close up to the stems of the trees. The result is, that already the annual growth of young shoots is perceptibly less and weaker, the fruits are, as regards numbers, about the same, but much smaller, there are more cracked ones, but



curiously enough the colour is richer. On closely examining the trees and their roots one finds them decaying near the surface, but making stronger growth in a downward direction. These conditions are more clearly defined in the sketch at *a*, *b*, *b* and *c*. The portion of soil shown at *b*, *b*, is the one that we always like to be well permeated with healthy, fibrous roots, so that we may have them under control, as it were, and at will, be able to feed them. Furthermore, where grass is allowed to grow close up to the stem of the tree, it acts as a splendid hiding place for all enemies of fruit trees—those, I mean, that every fruit grower wishes to exterminate. It is a very important matter, this clearing away of grass from fruit trees and I strongly urge it being done at once. If cultivators are not in a position to clear the whole of the ground occupied by their fruit trees, they should, at least, clear a space as shown at *d*. It is the next best thing. This cleared space should be quite 6ft. across, 9ft. in the case of large specimens in orchards. It will then be possible to water and feed freely, and to ascertain how the roots are faring.—G. G.

SOWING DUST-LIKE SEEDS.

IF we give due thought to the matter, it does seem wonderful that such magnificent plants as begonias, gloxinias, cinerarias and calceolarias result from the dust-like seeds that we sow. It often puzzles the mind of a beginner when engaged in sowing vegetable and flower seeds how deep he should cover each kind. Now, if lettuce, radish or pea seeds are sown deeper than is necessary, they will germinate and plants result. But if we bury these minute seeds too deeply, few indeed will germinate and penetrate the covering soil. Seeds of all the kinds named above—and of similar size—should be sown on the surface of prepared soil and not covered at all. Pans and flower-pots are better than boxes for these tiny seeds, because they keep the soil in a more consistent state of moisture. These receptacles and also the crocks should be washed and dried before use. On the latter place some half-rotted leaves or rough parts of fibrous turf, then fill up with a compost of loam, leaf-soil and sand, the two first named in equal proportions. Level the surface and firm the soil, then water

Digitized by Google

through a rosed watering-can. Allow the whole to settle for one hour, then sow the seeds on a sandy surface evenly and thinly. If a small quantity of sand is sprinkled on the surface, it shows up the little brown seeds more clearly. Do not apply water afterwards except by immersing the pot or pan, and till the seeds germinate keep glass and paper on the vessels. Until the tiny seedlings are well away in rough leaf very careful watering, ventilation and shading are essential.—HANTS.

THE TREATMENT OF FORCED BULBS.

QUESTION.—Are bulbs, such as those of tulips, hyacinths and narcissus, worth keeping after they have been forced?

Answer.—Yes, all of them except, it may be, the tulip bulbs that have been hard forced before Christmas. In their case I have found that, practically, the bulb is ruined and even if treated with the greatest care the results are not very satisfactory. So it is best entirely to discard such and devote time and space to bulbs of greater merit.

Question.—How should an inexperienced cultivator deal with forced bulbs to obtain the best results from them in after years?

Answer.—When the flowers are cut off, as much foliage as possible should be retained uncut. Of course, the growth has ceased for the present, so it would be unwise to apply water just the same as if active growth was going on. The forced bulbs have been growing and flowering in the greenhouse or conservatory and, at this stage, they should be taken to a cold frame, placed in it on a bed of ashes and left there unwatered till early March. Then place them outside, the pots on their sides, for two weeks or so. In the meantime prepare a border outside and plant the ripened bulbs in clumps or rows in it just the same as you would plant them in the autumn in the flower garden. Nothing further need be done besides keeping the soil clean. With the exception of the tulips, judging from my own experience, the bulbs will increase in strength for several years. I have had several square rods of ground literally covered with bulbs so treated and they have yielded great quantities of flowers for cutting. —G. G.

FLOWERS

LYCHNIS LAGASCÆ.

IN times past, when alpine plants were but few in gardens, Lychnis Lagascæ was much sought after and frequently attempted. I say "attempted" advisedly, for—one asserts it with confidence—the trials more frequently ended in failure than in success, and frequently a lament was heard from numerous would-be cultivators of this little Spanish plant. In too many cases a plant was secured in spring in a pot and planted in what seemed a good position. It flowered in due course, and the tyro deemed that he had established it. But when the next spring came he discovered that his lychnis no longer existed. To read the dictum of a well known expert, it should present no difficulty in a "rich *well drained* soil." But there have been many who have tried it under such conditions and have failed. Long experience has proved that L. Lagascæ requires the sunniest, driest chink in the rockwork, always provided that it receives water at the roots but is not soaked, and that the moisture can drain away almost as it reaches the roots of the plant. Some of the comparatively few places where I have seen it well established and flourishing have been in wall gardens with little soil behind and in full sun. It is not easy to become ecstatic over L. Lagascæ as it is usually seen. Although often described as "neat and compact," it is frequently rather spreading and loose-growing, with bluish green leaves and small but bright purple-rose-coloured flowers. There is a variety called L. L. rosea, which has paler flowers. The typical form can be raised from seeds or propagated by cuttings.—S. ARNOTT.

GREENHOUSE CYCLAMENS.

BOTH young and old cyclamen corms make new roots in spring and also while the plants are in bloom. Plants should be fed, therefore, when growth is active, then the foliage, flowers and corms will benefit. Cyclamens will only exist when potted in loam, but if set in leaf-mould and sand they make plenty of roots and good foliage. More satisfactory results can be obtained, however, when the corms are grown in a compost mixture of sand, loam, leaf-mould, charcoal and wood-ashes. After flowering, plants are subjected to various kinds of treatment according to the practice each cultivator may adopt. It may, therefore, interest readers to know that one plant which I kept isolated on a shelf for the purpose of seed bearing was never dried off, but was kept supplied with water. In the autumn I detached the seed vessels from the plant and sowed the seed in September of that year. From the seed I had a fine batch of healthy seedlings. The old plant was kept on the shelf and given water along with the other occupants of the house. In due course it produced fresh leaves and grew apace, till in the third week of January of the following year it had eighteen leaves and nineteen flower-buds, which were fairly well advanced at that time. The plant was in a 6in. pot and was not repotted in the autumn of the year in which it produced the seed, yet, strange to say, it was much better furnished with flower-buds and leaves than younger corms which were repotted in the autumn. The old plant was of a good habit and gave every indication of being of a floriferous nature, hence my object in procuring the seed from it. One of the seed vessels contained over forty seeds.—DAVID ARMSTRONG.

STARTING TUBEROUS BEGONIAS.

THESE are valuable subjects for furnishing the greenhouse—both the heated and the unheated structures—from April to November. For growing in the heated house the tubers may be started early in the New Year. For furnishing the cold house the tubers should be started about February 20th. For the benefit of the inexperienced I may say the right side of the tuber is the hollow or flat one, and this must be uppermost; the side to be partly buried in the compost is the rounded one. The new shoots—eventually stems—grow around the centre of the hollow; they at first are pale pink in colour, and care should be taken not to bruise or break them off. Very large old tubers may be cut into two, or more, parts, the cut portion being gently rubbed with charcoal dust. These cut parts should be embedded in a moist compost, but not watered before a few new roots are growing. The uncut tubers may be watered in at once, but all water should afterwards be withheld till the new roots grow, also the new shoots. I am now referring to the starting of the tubers in bulk in boxes; but where the amateur has plenty of small, empty pots I advise him to prepare them, fill with the compost, place a single tuber in each one, then keep the pots close together till new roots are filling those pots. The shift to larger pots can then be done without giving the least check to growth. Good fibrous loam, sand and leaf-soil in equal proportions make up a good compost for first use.—CHRISTCHURCH.

BOOK REVIEW

HERBACEOUS BORDERS FOR AMATEURS

SINCE the herbaceous border became an indispensable feature of every English garden, small or large, it has been dealt with at length by many authorities on flowering plants, but, unfortunately, much that has been written about it has been calculated to alarm and bewilder rather than encourage and assist the timid amateur. Mr. R. V. Giffard Woolley, however, in his recently published book, "Herbaceous Borders for Amateurs" (*Country Life*, Limited, price 5s. net), and a member of the new Gardening for Amateurs series of practical handbooks, shows a keen understanding of and sympathy with the difficulties—and the limitations—of the beginner. The scheme of this little volume is excellent in every way. In the introductory chapters Mr. Woolley treats of the proper preparation of the border in a very clear but simple manner, giving detailed but not over-elaborate instructions which can be easily followed by the most inexperienced amateur that ever struggled with a spade, while the advice given in a later chapter on the upkeep of the border is equally sound. In connection with this it may be noted that the author thinks a well prepared and planted border should not require re-making for at least five years, a far more reasonable term than the three which many gardeners regard as its limit of life.

The plate facing page 17 illustrates two pairs of well planned borders, either of which with the broad turf path dividing them would make an admirable 'lay-out," as effective as simple, for the long, narrow suburban garden to which it is so often attempted—quite unsuccessfully—to give an air of spaciousness by means of little curly-wurly paths, tiny patches of rockwork and minute shrubberies. It is indisputable that nothing makes a better setting for a herbaceous border, even if it be only one of the higgledy-piggledy kind which Mr. Woolley deprecates, than a turf path, and its obvious disadvantages may be minimised by a paved track down the centre or one on either side, as the author suggests. The last-named arrangement is the most practical, as it enables work to be carried out on the borders when the turf is too soft and wet to stand upon.

Of the trees and shrubs suggested as possible for background hedges some exception may be taken to the inclusion of hornbeam by reason of its retaining its dead and withered foliage throughout the winter, a habit which makes it useful as a shelter but an eyesore at the back of even a flowerless border, whereas an evergreen hedge is pleasing all the year round.

It is impossible to overpraise the tables of suitable border plants, which fill a considerable proportion of Mr. Woolley's book. Not only do they give full particulars of colour and height, but there are cultural notes which, although brief, are lucid and sufficient. The lists in question have, obviously been made out with great care, and are at once catholic and comprehensive; but there are a few omissions, of which the most important are the two fine potentillas Gibson's Scarlet and Miss Willmott (rosy pink), Lychnis Flos-cuculi fl.-pl. (rosy pink), Geranium grandiflorum (blue) and Trollius asiaticus (orange, and a better plant than T. europæus).

The suggestions for border colour schemes are very attractive as well as practical, and may be specially commended to the attention of the amateur. Indeed, if the latter will take this little volume as his guide and carefully follow out the instructions contained in it he cannot go wrong no matter how slight may be his previous acquaintance with its subject. R. E. H.

FOGWILLS WONDER LONG-POD BROAD BEANS

Ten Beans in a Pod.
WONDERFUL FREE GIFTS.
NOW IS THE TIME TO SOW FOGWILLS WONDER LONG POD. The LONGEST, most PROLIFIC and FINEST FLAVOURED BROAD BEAN in the World. Nothing like it. Nothing just as good—PERFECTION. 1/4 per pint, carriage paid. Send now; every customer will receive three FREE GIFTS as follows—1/- packet (2,000 seeds) FOGWILLS FAMOUS GIANT EXHIBITION BRUSSELS SPROUTS, largest, most magnificent solid sprouts in cultivation, and FREE, a 6d. packet (1,000 seeds) FOGWILLS PRIDE OF THE VALLEY PARSNIP grown over 50 inches long, and FREE one packet (100 seeds) FOGWILLS GIANT RAINBOW SWEET PEAS, large waved flowers in over 25 shades. Send only 1/4 for this wonderful FREE OFFER and become one of our THOUSANDS of satisfied customers.
Fogwills 'Best-Result' Seeds need only a trial.
Fogwills Beautiful Illustrated Catalogue of "Best-Result" Seeds and Guide to Garden Success for Season 1926. Now Ready. Post Free.
FOGWILLS, Established 70 years. 130, FRIARY STREET GUILDFORD. Awarded Gold Medal.

HILLIER'S
FRUITING TREES
Special Offer of Specimen Trees at Reduced Prices to clear ground.
STANDARD CHERRIES, 6ft. stems and extra large heads, with plenty of fine roots .. 10/6 each
Early Rivers, May Duke, Kentish Pie, etc.
EXTRA LARGE BUSH CHERRIES .. 10/6 each
May Duke, Morello, Kentish Pie.
STANDARD FAN-TRAINED PEARS in several varieties .. .. 42/- each
ESPALIER PEARS on Pear stock, four and five tiers, perfect trees .. .. .. 10/6 and 12/6 each
Beurre Diel, Louis Bonne of Jersey, Pitmaston Duchess, Catillac.
EXTRA LARGE BUSH APPLES, on broad-leaf Paradise stocks.
Crimson Bramley, 5-5½ft. 8/6 and 10/6 each
Encore, 6-7ft. .. .. 10/6 and 12/6 each
Newton Wonder, 5-5½ft. .. 8/6 and 10/6 each
PYRAMID PEARS on Quince stock in variety .. .. .. 8/6 and 10/6 each
STANDARD AND HALF STANDARD MEDLARS, PEARS AND GOLDEN BULLACE .. .. 8/6 and 10/6 each
BUSH PLUMS. List of sorts on application .. .. 8/6 and 10/6 each
Full particulars of the above on application.
Carriage paid on all orders value £5 and over up to 100 packing at cost.

AUTUMN and WINTER BEAUTY
In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.
There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.
What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.
We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.
THE BARNHAM NURSERIES, LTD., BARNHAM, SUSSEX.

For success in your Garden USE
THOMSON'S MANURES
On the market for over 50 years, they still hold first place for QUALITY and RESULTS. They are safe, sure and lasting. The direct result of many years' practical experience in gardening, they stand unrivalled at the present day for all Garden Crops.

MUSHROOMS IN NATURE.

THE popular interest in mushrooms and toadstools seems to be increasing on the Continent. Before the war, only in France did a non-botanical public give much consideration to them, though in most countries a considerable number of species have long been sold in the markets. Scarcity of food during the war, particularly in central Europe, was apparently the reason for greater attention being paid to edible fungi. However this may be, there has been considerable increase in popular writings on the subject and two or three "semi-popular" periodicals are now published. Switzerland shares in this increase in amateur interest—as distinguished from the purely scientific—and the appearance of this very attractive book, "Les Champignons Dans la Nature," by J. Jacottet. (Delacroix and Niestlé, S.A., Neuchatel. Seventy-six coloured plates, forty-seven text figures, 243 pages, price 30 francs), will doubtless encourage many to mycology, which, apart from purely gastronomic aspects, presents problems as enticing as those of any group of alpine plants. In a work of this kind attention is naturally first drawn to the illustrations. It is difficult for beginners to grasp the essentials of specific descriptions from verbal descriptions of agarics; and illustrations are sometimes more misleading than helpful. The seventy-six plates in the book under review, depicting 115 species, are among the best existing. They are by Paul Robert, Fils, and show the fungi in their natural habitats, but so arranged that the characters of the species are clearly seen. In addition to the plates, there are forty-seven attractive line drawings (by Dr. E. Jacottet) in the text.

After a preface by the well known Swiss mycologist, Dr. C. E. Martin, the author has an introduction in which he comments on many interesting facts about fungi. In it he considers some of the traditional methods of distinguishing between edible and poisonous species—and all mycologists will agree with his conclusion that there is no other way of telling whether a species is edible or poisonous than that of precise determination according to their botanical characters. Here is also given a summary of classification. The main portion of the work deals with the larger fungi only. The method adopted to give a somewhat detailed description of the more interesting species—these being usually the subjects of the coloured plates—and other species are grouped round these. Full details of the discomforts following the eating of the poisonous species are recorded and the best recipes for cooking are given in the case of edible species. Although the gastronomic side bulks largely, there is a considerable amount of useful information as to the habitats and seasons, which shows the author to be an experienced field mycologist.

In addition, there are frequent references to facts which are not always dry as dust: *e.g.*, it is stated that the Chanterelle used to be sold by weight at Geneva, but that as the market people soaked the fungi in water—which leads to fermentation—it was decided that they should be sold by measure. The printing and paper are excellent, the binding is rather of the Christmas gift variety, and the guard paper is decorated with Sepultaria Sumneri, a discomycetous fungus, which appears exclusively under cedars. One gains the impression that author, artist and publisher have thoroughly enjoyed themselves in the production of the book.—J. R.

CATALOGUES RECEIVED.

The spring catalogue of Messrs. Dobbie and Co., Limited, is both interesting and useful. This firm, whose reputation in connection with sweet pea growing and potato raising is world-famed, includes countless varieties of both these in its catalogue. The vegetable garden, as well as the flower garden, is well catered for, and those who are seeking guidance in selecting the best varieties to grow will find much helpful information. Numerous excellent half-tone illustrations and useful cultural details are given.

Mr. Alfred Dawkins, 408, King's Road, Chelsea, London. A catalogue of flower and vegetable seeds, lawn seed, fertilisers, tools, secateurs and other horticultural sundries. An interesting list of floral and vegetable novelties for 1926 is also included.

Messrs. John E. Knight and Son of Wolverhampton send us a catalogue of flower and vegetable seeds. It is illustrated by many half-tones and reproductions in colour. The lists are well classified and the hints on cooking vegetables, as well as growing them, should be found very helpful.

Mr. W. E. Th. Ingwersen, The Birch, Sharpthorne, Sussex, sends a most interesting seed list. Seeds of alpines, hardy plants and certain trees and shrubs are offered, and all the seeds are guaranteed to be new and harvested this year. Many of those included are not listed in the catalogues of the general seedsmen.

Messrs. T. R. Pearson and Sons, Limited, The Nurseries, Lowdham, Notts. A well printed and well illustrated catalogue dealing chiefly with flower and vegetable seeds. Careful descriptive and cultural details are given, also clear, practical directions for the growing of mushrooms. This catalogue will prove of great interest to the amateur gardener.

Messrs. Dickson, Brown and Tait of Manchester have sent us their catalogue of garden seeds and it is evident that they are maintaining their high reputation as first-class seedsmen. There is a wide choice both in vegetable and flower seeds. Innumerable varieties of each kind are listed and many half-tone illustrations are given.

The well known Scottish firm of Messrs. Austin and McAslan of 89, Mitchell Street Glasgow, have published a useful and well arranged catalogue of garden seeds, bulbous plants and sundries. A fine selection of sweet peas and begonias of all types is given. The colour descriptions of the various varieties are good and most helpful. Such a long established and noted firm as this one can be well recommended.

A manual of garden seeds issued by Messrs. Fisher, Sons and Sibray of Handsworth, Sheffield, has just come to hand. Annuals for beds and borders are stocked in plenty, and all the popular flower seeds are sold by weight. One section of the catalogue deals with gardeners' and foresters' tools and implements, and in it are listed a number of handy and useful tools at most reasonable prices.

Stewart's "Stronghold" Seeds are known to many gardeners and their high quality fully realised. In the catalogue of this firm are to be found lists of annuals and perennials of all kinds to be raised from seed, bulbs and roots for spring planting, a selection of Scotch seed potatoes, lawn seed, sundries, etc. The information therein should prove of great service to the amateur. Their address is Messrs. Stewart, 13, South St. Andrew Street, Edinburgh.

Messrs. Little and Ballantyne, the Carlisle seedsmen, send us their catalogue of garden seeds of guaranteed purity and germination. Comprehensive lists are given and many novelties are included. The amateur will find the brief cultural details very useful. The reliability and fine quality of the trees and shrubs sent out by this firm have gained for them a high reputation, and we can assure our readers that the seeds supplied by them are of the same standard.

We have much pleasure in bringing to the notice of our readers the seed catalogue of Messrs. W. H. Simpson and Sons, the firm of antirrhinum fame.* Anyone who has seen the antirrhinum exhibits set up by Messrs. Simpson can appreciate the excellent strain of these invaluable plants which they have obtained after many years of selection. Their address is Chad Valley, Edgbaston, Birmingham.

The Dallin seedsmen and nurserymen, Messrs. W. Drummer and Sons, have published a 1926 catalogue of garden seeds. It is a comprehensive and interesting one. The careful cultural hints will be found most helpful.

Messrs. Robert Veitch and Son of 54, High Street, Exeter, send us a catalogue of garden seeds. Vegetable and flower seeds are given and also an interesting list of a number of recent floral introductions. All keen gardeners should write for this catalogue.

Messrs. Barr's seed guide for 1926 should make a wide appeal. The specialist as well as the amateur is well catered for. Many fine perennials, and nearly two hundred specialities for the year are included. Among them will be found rare alpines, hardy perennials, annuals and greenhouse plants.

A selected list of trees and shrubs, which are at their full beauty during the autumn and winter, are offered by the Barnham Nurseries, Limited, of Barnham, Sussex. Deciduous shrubs with coloured foliage and stems, berried shrubs, winter-flowering shrubs and a few evergreens are listed. The prices quoted are most reasonable.

Messrs. Cooper, Taber and Co., 90, Southwark Street, London, S.E.1. A comprehensive wholesale seed catalogue.

FOREIGN.

Messrs. Carl Beck and Co., Quedlinburg, Germany. A catalogue of vegetable and flower seeds.

The Royal Horticultural Society invites entries for the following trials to be carried out the coming season in the experimental gardens at Wisley, *viz.*, Culinary peas (midseason varieties only), kohl rabi, cabbages for spring sowing, savoys, celeriac, maincrop potatoes, aubrietias and the following annuals: calandrinia, cosmea, everlasting flowers, linum, nemesia, lavatera, nigella, nemophila, portulaca, sweet sultan, viscaria. Seeds, tubers and plants for these trials should be sent so as to reach Wisley by January 31st, 1926. They should be addressed to The Director, R.H.S. Gardens, Wisley, Ripley, Surrey. (Goods *via* Horsley Station, Southern Railway.) Each article entered must be accompanied by an entry form duly filled up. Copies of the entry forms can be obtained from the Director.

New Carnations Registered with the British Carnation Society.—"Kathleen Simpson": Mr. A. J. Pointing, Appleton Nursery, Bulpham, via Romford. Parentage, seedling. Enchantress x Wand. Rich cream shading of apricot. Size 3ins. Fragrance very slight. Habit and stem good; calyx good. "Winnie Pointing": Mr. A. J. Pointing, Appleton Nursery. Parentage, seedling. Wand x Triumph. Deep cerise, 2½ins., mild fragrance. Habit very free and stem good; calyx very good and seldom splits; also very easy to grow, and the cuttings strike freely. "Joan Henderson": Lady Brodie Henderson, Epping House, Hertford. Parentage, seedling. Large, good fragrance. Habit and stem good and strong. The growth is good, and it seems to us that it should be a good doer.

GREENHOUSE ANNUALS

WHERE annuals for the greenhouse were not sown during September, a start should be made this month. Seed in most cases is best sown in a house with a temperature of 50° to 55°, using shallow seed boxes, pans or pots. It is very essential that thin sowing be practised, or damping off is almost sure to prove troublesome. They should be pricked off as soon as they are fit to handle. In some cases plants may be put singly into small pots, while others may be put into boxes some 2ins. apart until they are arge enough to pot off singly. Statice Suworowii, acrocliniums, rhodanthes and mignonette are a few examples of plants that are best transferred in a small state

directly into small pots, as at any time they are impatient of root disturbance. The acrocliniums and rhodanthes should be put directly into their flowering pots, putting ten to twelve plants in a 48-sized pot. Any of the popular annuals may be sown from now onwards, remembering always that they must be grown perfectly cool, any attempt at coddling them resulting in weak growth.

Some of the most popular and useful annuals for cool house work include Browallia viscosa, clarkias and godetias, also Collinsia bicolor, Linaria aparinoides, L. maroccana and L. reticulata aureo-purpurea, Nemesia strumosa in many fine varieties, Nicotiana Sanderæ and schizanthus. There are, of course, many more beautiful and interesting annuals that can be used for this purpose.

STREPTOCARPUSES AND GLOXINIAS

IF seed is sown during January, the resulting plants will prove very useful for the greenhouse during late summer and early autumn. When sowing seed the method

Robert Sydenham Limited

Please mention THE GARDEN when writing.

usually practised for begonias, should be followed, although their ultimate cultivation is somewhat different. The young plants should be grown steadily on in a temperature of about 60° in their younger stages. As they increase in size and the season advances they should gradually be accustomed to cooler and more airy conditions, shutting them up early in the afternoon with plenty of sun heat.

Streptocarpuses raised in this way last year, and kept fairly dry and warm during the winter, should now be shaken out and re-potted in a light, rich compost, watering them carefully until they have made a quantity of fresh roots. Such plants should make fine large specimens for summer flowering. A batch of dry tubers of gloxinias may be

started in a warm house towards the end of the month. They should also prove useful for summer flowering.

EARLY TOMATOES.

JUDGING from experience, cultivators of tomatoes mostly make a resolution to grow the plants and so have ripe fruits earlier each year. Sometimes it is possible to do this and, as early fruits are so highly appreciated, it is well worth while sowing a few seeds early. But this should be done only where there is sufficient heat available from pipes. If it is not possible to keep out frost without "driving" the little heating apparatus, then refrain from an attempt to grow very early tomatoes. The seeds for the latter should be sown early in January; where moderate heat only can be commanded, sow the seeds at the end of February—about the middle of that month if the glass structure is situated in a very warm position. Sow each seed singly, either in tiny holes made with a pointed stick, or about 1in. apart on the surface of the soil and then cover them about a quarter of an inch deep with soil, not sifted too finely. I dare say some readers have had experience of seedlings damping off wholesale in a fine soil. There would be less loss from this cause if the compost was of a more lumpy character, with bits of old mortar rubble mixed in. If small pots are available, I advise the sowing of two seeds in the centre of each one; then the removal of the weakest, if both germinate, and a re-potting in due course without disturbing the roots. The small pots are placed close together. It is important that good old fibrous loam be used and not any from boxes as there is a danger of fungus spreading. The plants should be fruited in 9in. pots, the soil in them being added to from time to time.—G. G.

Seedlings Thrive and Don't Die

off after being transplanted owing to root disturbance or breakage, if brought up in Patent

MILLIONS SOLD **T. P. SEED RAISERS** NO SLUGS

because no disturbance can take place.

FOR ANNUALS, as Godetias, Clarkias, Larkspur, etc., *USE* **BABY T.P. SEED RAISERS** (measuring 1¼in. across by 2in. deep). Sow 2 or 3 seeds per Raiser, pull out to strongest. It will develop strong root growth till planting-out time comes, when Raiser (by that time rotted) will peel off, allowing seedling to be put in soil without knowing it has been touched.

FOR SWEET PEAS *USE* **T.P. PEA RAISERS** (size 1¾in. across by 4½in. deep). Sow 1 seed per Raiser. You will be delighted with good root action and quick development after planting out.

You get stronger plants, guaranteed to grow well with less labour.

T.P. Raisers take up much less room and retain moisture thus requiring less watering, are easy to handle in bulk and do not break, and ensure good plants, thus saving seed wastage.

PRICES in U.K., cash with order, carriage paid—

Baby "T.P. Seed Raisers, one strong seedling tray with 54 "**Baby**" Raisers complete. 1 for 2/6; 2 for 4/9; 3 for 6/9; 6 for 13/-; 12 for 24/6. **Refills** ("**Baby**" size), 108 for 2/7; 216 for 4/10; 324 for 7/3; 540 for 11/3.

T.P. Pea Raisers, one wooden box having hinged side with 48 Raisers complete. 1 for 4/3; 2 for 8/-; 3 for 11/6; 6 for 22/6. **Refills,** Pea size, 100 for 3/-; 200 for 5/9; 300 for 8/3; 500 for 13/6

Order NOW from your Seedsman. If he does not stock, send direct to Sole Makers

AUTUMN and WINTER BEAUTY

In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

DISTRICT FLOWERS

WE are inclined to grumble at the climate of these islands, but the more I see of them the more certain I am that no country in the world can produce conditions so admirably suited for gardening. And such variation, too. There are gardens where the winds blow and the cold is arctic; there are gardens where sub-tropical vegetation rampages as it does on the Mediterranean. I visited last autumn a garden where not only do olives grow out of doors, but flower and fruit, and where the lady of the house makes marmalade from her own oranges ripened outside in her own garden. In this garden gums and acacias grow better than on the Mediterranean. In the middle of November, when I saw them, a few acacias were bursting into blossom and every bush and tree of many varieties was covered with buds.

I had always heard of Porloch as a tropical oasis planted in our isle, but I had taken everything I had heard with a grain of salt. Now that I have seen it I know that what I had heard was only part of the truth. Passiflorus, Lonicera Hildebrandtii, Buddleia Madagascarensis, the tree tomato and dozens of other sub-tropical plants flourish magnificently out of doors.

But I must not rhapsodise too much on the conditions at Porloch.

What gardeners, perhaps, do not sufficiently realise about the British Isles is the variation of climate and temperature in various neighbourhoods. A degree or two may make or mar the perfection, not only of one, but of dozens of plants. Every neighbourhood, whatever its climate may be, will be pre-eminently suited for the cultivation of certain plants, and yet one does not often see an intelligent appreciation of this fact. It is far from my intention to belittle the standard flowers that have made our gardens famous throughout the world, the roses, irises, sweet peas, stocks, hollyhocks, and all the hundred and one gems that make the backbone of our horticulture. There is, however, in every neighbourhood, some genus which is suited, above all others, to the particular climatic conditions prevalent there, something that should be most extensively planted and would set the seal on that part of the country. In a few cases this has already been done. Take Cornwall as an example. What is at once thought of when Cornish gardens are mentioned? Rhododendrons—and then more rhododendrons. There is no county in the British Isles, and probably no country in the world, whose climate suits them so thoroughly.

Last autumn I made a short tour through Devon and Somerset, that area where the landscape is cut with deep sheltered wooded coombes, where the sea air tempers the cold, and where the valleys are frequently sheltered from the fiercest gales. I am more than envious of a climate that allows the successful cultivation of such an amazing range of plants. I am also struck by the fact that many people do not make use of the climate that lies at their door. Perhaps they do not realise the potentialities of gardening under such conditions. When hundreds and thousands of gardeners envy one one's climate, it is unfair not to make use of it. I do not mean that every new sub-tropical plant should be tested, for that is running to the other extreme, but there are a number of plants, both new and old, that are eminently suited to the normal Devonshire conditions which might be more grown.

Two of these are already much in evidence in cottage gardens—and there is no surer sign of the value of a plant than its existence in gardens where every foot of space is valuable. One is the creeper Solanum jasminoides, which I noticed flowing in cataracts of blossom down many a cottage wall. The other is the fuchsia. If any plant should be called Devonshire's pride it is that. Here is no Will-o'-the-Wisp that has suddenly appeared and in our first enthusiasm has taken a place in our affections which it does not deserve. Rather it is an old favourite that has fallen into an undeserved decline. There has been a certain amount of correspondence lately in THE GARDEN on the fuchsia and I can fully bear out the praises of its admirers. For colour and liveliness, there are few shrubs to touch it, whether you choose tall-growing species, brilliant large-flowered hybrids or the tiniest, like F. procumbens. I prophesy a great rebirth for this genus's popularity. It is not a difficult prophecy, for I am betting on a certainty.

Although it is especially suited to Devonshire and its surroundings, yet a number of them are hardy enough to prove a joy elsewhere. The trouble is that most of them have disappeared from trade, although I would guess that every variety that was ever known was to be found in some little garden or other in Devonshire. Luckily I found a fuchsia enthusiast and am going to try a number of them in Scotland from cuttings. If they do not thrive outside, they are an ornament to any cool greenhouse. In one cottage garden I saw three bushes of fuchsia, each laden with pendent blossoms. Each was of a different variety and each possessed a subtle, elusive quality of its own. Two I did not recognise, but the third was undoubtedly that fine old favourite, Venus Victrix.

Whatever the kind, the fuchsia is undoubtedly the plant for Devonshire. It can be grown in hedges, in clumps or as specimen plants. Why is it not more grown? It should be seen in masses in every garden, large or small. It is so obviously Devonshire's flower.

Two other shrubs I noticed that are worthy of extensive planting in those parts, the manuka or leptospermum and

Digitized by Google

various myrtles. There are few berried shrubs to beat Myrtus Ugni when it is laden with its deep crimson berries, that taste like a strawberry and make, so I am told, excellent jelly. This last I only saw in one of the most sheltered of gardens and, as I have had no experience of it, I cannot vouch for its hardiness, but those who know Dartmouth College, may remember the four fine myrtles in front and a more windswept spot it is hard to imagine.

I have taken Devonshire as an example, but in every neighbourhood local gardeners who have experience of local conditions, *must* know of a plant or plants that are superlatively successful in their neighbourhood. People are often too much inclined to follow the general fashion, whether the fashion suits them or not, and ignore the particular successes of their district if these do not happen to be in the public eye at the moment. E. H. M. C.

THE FIFTY BEST ROCK PLANTS

BY DR. R. LLOYD PRAEGER.

THIS Fifty Best So-and-so stunt is tolerable chiefly on account of the controversies which it inevitably provokes; these controversies drag out a number of individual opinions and thus discount the dogmatic limitation which the title suggests. But a discussion as to the fifty best of any class of plants is to a large extent futile; there are a dozen or more "fifty bests," according to the different climates, soils and so on which are to be found within even such a small area as the British Isles—not to mention the very important factor of individual preference. This last factor can be, and often is, eliminated by taking a plebiscite; but the obstacles of climate and soil persist. And even in so limited a subject as rock plants, the choice still remains indefinite, for the aims and ideals of different rock gardeners vary much: one man, A, aiming at square-yard patches of glowing colour, while another, B, finds his heaven among small, difficult primulas and androsaces. While A dazzles you with a rampant waterfall of "Dr. Mules" or Guildford Seedling, B reverently uncovers to your gaze a scrap of Eritrichium nanum that is not yet quite dead. No list of fifty best plants would ever satisfy both A and B; and, even though most rock gardeners are of an intermediate cast of mind, the choice remains difficult, since the factors of freedom of growth, beauty (which includes several qualities, from showiness to daintiness), interest and rarity have different relative values to different minds. It will be better, perhaps, to consider separately the aspirations of A and of B.

Take the case of A first. Owing to natural inclination, or to want of time, or to a soil or aspect unsuitable for difficult things, or to a superfluity of cats, or to a situation demanding a bold display, his needs are plants of free growth—good showy things that will give little trouble and plenty of bloom—the kind of rock garden, in fact, that is founded on the Three A's (in capital letters)—alyssum, arabis and aubrietia. Without going to the length of explicitly specifying fifty plants, it is easy to indicate the sources from which his "fifty best" should be derived. But in making (or in criticising) this and the following lists it is necessary to clear our minds of gardening cant, and especially not to think less of a plant because it is common, or more because it is rare or difficult: its intrinsic merit as a decorative plant is all that concerns us:

Arabis albida and var. flore pleno.
Alyssum saxatile and var. citrinum.
Aubrietia according to choice.
Armeria—preferably plantaginea and maritima Laucheana.
Achillea, such as moschata and umbellata.
Arenaria montana and balearica.
Androsace lanuginosa and sarmentosa.
Acæna, dwarf ones, especially Novæ-Zealandiæ.
Anemone nemorosa var. Robinsoniana.
Campanula, such as garganica, garganica hirsuta, Portenschlagiana, pusilla, rotundifolia vars.
Coronilla cappadocica.
Dianthus, such as cæsius, petræus, plumarius, suavis and varieties.
Dryas octopetala.
Erodium Manescavii, trichomanæfolium macradenum, etc.
Geum montanum.
Globularia cordifolia.
Horminum pyrenaicum.
Hypericum reptans, olympicum, etc.

THE CHEDDAR PINK, A NATIVE, AND ONE OF THE BEST OF ALL ROCK PLANTS.

Digitized by Google

OXALIS ENNEAPHYLLA ROSEA MUST BE INCLUDED.

ANEMONE NEMOROSA VAR. ROBINSONIANA.

Oxalis rosea.
Phlox subulata in variety.
Saxifraga—red, pink and white mossies; silvers like Cotyledon and Aizoon; the most vigorous kabschias, namely, apiculata, apiculata alba, sancta; umbrosa var. primuloides, Andrewsii and a megasea or two.
Sedums—a selection, such as Ewersii, populifolium, sexangulare, purpureum, spurium splendens, roseum, Ellacombianum, kamtschaticum, stoloniferum.
Sempervivum in variety (*e.g.*, arachnoideum, hirtum, ciliosum, calcareum).
Thymus Serpyllum vars. coccineum and album.
Veronica prostrata, filiformis, and a few of the dwarfer New Zealand shrubby species.

Of course, anyone can pick holes in this list, but it will serve as a basis, all the same, and the rock gardener who wants a free-and-easy collection which will give little trouble and will make a good show will not go far wrong in following it—using his own judgment, of course, in view of his particular requirements and limitations. It will provide him with a fair variety as regards colour, form and size, and of sun and shade loving plants, which have no special requirements as to soil.

(*To be continued.*)

GARDENING IN SINKS AND PIG TROUGHS

BY CLARENCE ELLIOTT.

IT might be imagined if one had not tried it, that growing alpine plants in pig troughs was an incongruity almost as hideous as the casting of pearls before swine, and that no worse place could be chosen for the making of a rock garden than a scullery sink. Not so.

I have been gardening in stone troughs—pig, sink and otherwise—for many years, ten or twelve at least, and the more I do it the more possibilities do I see for fresh and enchanting developments. True, I have only tried rock gardening in my sinks, but it occurs to me that one might have great fun experimenting with other classes of plants. For instance, you might have a bulb garden, a massed medley of scillas, crocus species, miniature narcissi (triandrus, cyclamineus, minimus and the rest), muscaris, chionodoxas, fritillarias, etc.—a whole meadow of spring blossom. But what of the summer? you ask. For summer show you could grow any one or any dozen of a wide range of annuals. You could grow portulacas to perfection or those marvellous jewel flowers the leptosiphons. Or, most interesting experiment of all, you might sow a carefully chosen mixture of dwarfish annuals, and, by sowing thickly and thinning out to exactly the right degree, not removing a plant too many, you could induce them so to crowd and dwarf one another that they would produce the effect, in miniature, of a flowery meadow of brilliant colour such as one imagines growing wild in California. In this way one might try the annual linums, papavers, leptosiphons, nigellas, gilias, Virginia stocks, China asters and so on. With a few packets of annual seeds and just the right degree of crowding, you could contrive wonderful effects.

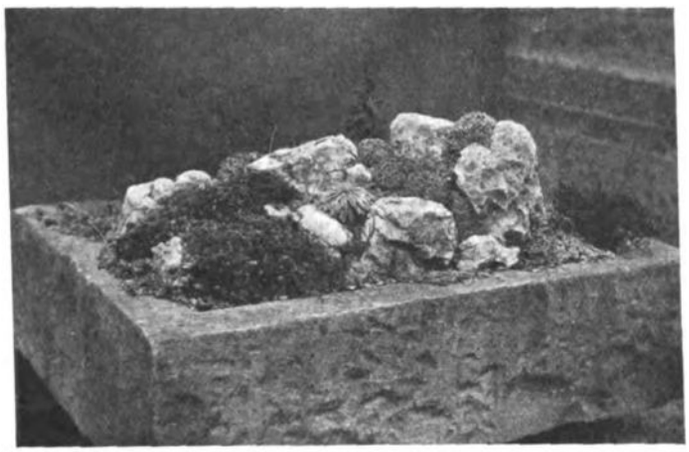
Another idea! A new and delightful way of growing succulent plants. With a few rough rocks, simply arranged, what a fine picture you might make with a collection of eight or nine different kinds of echeverias and cotyledons. The great drawback to the cultivation of these plants hitherto has been that they have seldom, if ever, been allowed to assume a natural permanent air of their own. But your sink succulent garden will be a permanent affair, for, being portable, you can stand it out in the open air from May till October, and then, when frosts threaten, you can have it carried bodily into winter shelter—a cold greenhouse or a cold frame. Some of the dwarfer forms will hug close to the rocks and spread down over the edge of the sink. The old Echeveria secunda will be splendid for this purpose, and how much happier it will look, than it has ever been allowed to look in the past, drilled and dragooned into carpet bedding by a bygone race of gardeners, who seemed to have missed their vocation and ought to have been sergeant-majors.

The sink rock garden of alpine plants does not entail any periodical shifting. Once you have chosen the right place for it, there it may remain, winter and summer, for your alpine plants need no protection of any kind.

And now, having written round and about these new developments of sink gardening, I had better go right back, and starting, so to speak, at the "first catch your hare" part

Digitized by Google

of the subject, tell how to set about the business of rock gardening in stone troughs. First, then, you must find your sink, pig trough or what not, and here the one important thing is that it must be of stone. The shape does not so much matter, nor its size. Once you start, you will soon find yourself collecting troughs of every size and shape, and all are delightful. The best place to hunt for stone sinks is in builders' yards. Old stone pig troughs may often be picked up around farms and cottages. Stone pig troughs are of all shapes, sizes and weights, and the best of them are delightfully rugged. Glazed earthenware sinks are not good. They are ugly, and they lack the porosity which makes stone so congenial to the roots



A WELL ESTABLISHED SINK GARDEN.

of the plants. Concrete troughs should be avoided like the plague. They are an expensive and ugly substitute for stone, and the more you attempt to make concrete look like stone the uglier and more insincere the fake becomes.

In almost every case you will find the need of having your sink raised off the ground. Sometimes a good resting-place is to be found on the coping of a low terrace wall. But failing any such ready-made position, the simplest thing is to make for each sink a couple of rough stout piers of stone or old bricks about 9ins. to 12ins. square and 18ins. to 2ft. high, and stand it on these.

Needless to say, an outlet hole must be provided in the bottom of each trough for drainage. Pig troughs do not, naturally, possess them. Sinks, on the other hand, have their own outlet holes through which they were wont to evacuate slops in the days before they were promoted to the garden. One important matter, though, I must mention in connection with drainage. Having placed your sink in position, make sure that it is at such a tilt that it will completely empty itself of water. Pour water in while it is empty, and if all is not as it should be, it is easy to pack up the low end to exactly the right level.

Apart from this, drainage is a simple matter. A big crock or two arranged over the outlet hole and an inch or so of smaller crocks spread over the bottom of the sink and over these again a layer of rough turf fibre. It only remains now to put in your soil. Arrange your rocks and choose and place your plants. For soil make a gritty, fibrous mixture. Good live loam, silver sand, leaf-mould, a suspicion of peat and plenty of broken stone chips or smashed-up flower-pots. These last are excellent. They are so sharp and porous. Use them from the size of split peas down to such dust as occurs in breaking. Broken charcoal is another luxury you may add—not essential, but good. It keeps the mixture open and sweet. Now for the rocks. And here I really am up against a difficulty in trying to tell you how to build your rock garden. It is as difficult as telling how to paint a picture. The stones must not look as though they had just seen a ghost. They should sit down in the soil like a contented cat. Aim at a little rocky outcrop, higher at one end than the other and more precipitous at the high end than the other. Build your rocks together, aiming to make them look like *one rock* which has been split into seven or eight pieces by a series of irregular cracks. This rock outcrop will now be sitting on a floor of soil, its base an inch or two below the edges of the sink. Now fill up the sink to the brim with soil, and pour and pack soil into the cracks between the rocks. This filling up of cracks and hiding of the bases of the rocks pulls the whole composition together and does more than anything else to make the arrangement appear one coherent whole. And now you are ready for planting. Almost certainly you will want a tree or two, but they must be chosen with care and placed with tact. The best tree of all is undoubtedly the tiny Juniperus hibernica compressa, dainty, compact, bolt upright, blue green, full of character. The first unthinking temptation is to plant this juniper on the summit of the hill. But that is not the best place. Find, rather, a comfortable spot for it somewhere about two-thirds down the slope of your hill. Another splendid tree is that dwarf variety of the Scots pine called Pinus sylvestris beuvronensis. It is rare and a little difficult to come by, but a small specimen should be secured if possible and planted so as to lean out sideways from some cliff on your outcrop. It is difficult to place it thus without making it look stiff, but a season's growth will correct this, and soon the leaves and branches will grow to their position and look natural.

Other good conifers are some of the dwarf retinosporas, especially RR. obtosa nana and pygmæa, also R. pisifera nana. Another to try is that rare and romantic tree which Farrer sent home from his last expedition, the coffin juniper. This in nature is a gigantic forest tree, but it is a slow grower and of graceful weeping habit, and small specimens might safely be used. Then there is that quaint dwarf form of ivy, Hedera conglomerata prostrata. It grows in an odd huddled way and is good for a carefully chosen corner at the foot of a rock.

FLOWERS IN THE SINK GARDEN.

I will name some of those which I have found best, and tell of their wants and the positions which suit them best. Let us consider first the level ground between the base of the rock and the edge of the sink, and I will assume that in some places the rocks come to within an inch or even less of the sink side, while elsewhere you have left irregular spaces anything from 6ins. to 18ins. across. Your best plan will be to plant the opener, level spaces with carpeting, mat-forming plants, to make a sort of grassless alpine flower lawn, and in the narrower crevices between rock and sink some close growers, with here and there a trailer to hang and partially clothe the sink side.

For lawn effect I recommend Gentiana verna, Thymus Serpyllum minus, a minute creeping thyme; Claytonia australasica, with a turf of fresh green leaves like grass a quarter of an inch high and almost stemless white flowers. Erigeron leiomerus gives the effect of a lilac daisy an inch or so high; Bellium minutum (Little Mary), which is a white daisy less than an inch high; Primula minima, a fine turf-maker, with big, rosy flowers, erect and almost stemless; P. farinosa, rather taller, with heads of lilac-pink flowers; and P. scotica, a dwarfer edition of it and darker in colour; Androsace carnea, pink; Viola Bertoloni, lavender blue; and Polygala calcarea, mat-forming and brilliant blue; also Anemone vernalis. Among these turf plants you may put some of the smallest of the bulbs—crocus species, such as C. Sieberi, C. reticulatus, etc.; Iris Histrio, I. histrioides and I. Danfordiæ, very early and brilliant yellow; Narcissus Bulbocodium, N. cyclamineus, N. minimus and N. triandrus. Also the lovely Oriental alliums, A. cyaneum, A. Farreri and A. Purdomi, which carry their heads of lavender-blue flowers like fairy agapanthus on 4in. to 6in. stems. All these and many others—to taste—to form a flowered lawn on the lowest levels. As plants to trail down the sides of the sink, I suggest the following: Saxifraga apiculata, S. a. alba, primrose yellow and pure white respectively; and S. Haagii, golden yellow, and all flowering in earliest spring; Dryas octopetala, with its lovely flowers like white anemones; Androsace lanuginosa, silky leaved, trailing and with heads of lilac flowers in late summer; Polygonum vaccinifolium, again for late summer and autumn, with slender rosy flower-spikes and crimson autumn leaves. Achillea Lewisii will make a mat to bulge out over the sink side, and this good plant will go on producing its pretty sulphur-yellow flowers from early till late summer, and often after that. Arenaria purpurascens will trail forward if pushed from behind by a rock, and it covers its mossy cushion with charming lilac star flowers. If you want a mat of violet, try Calamintha alpina. The old Cheddar pink, Dianthus cæsius, will give you a mat of blue-grey with rose pink fragrant blossoms. Hypericum reptans is first-rate, spilling from the

Digitized by Google

sink in a thin stream of fresh green, with big stemless flowers nearly an inch across, citron yellow and stained behind with a reddish flush. An extremely choice and lovely plant and, alas! expensive, is Linum salsaloides prostratum. It forms a dense low mat of heath-like foliage, and then, in summer, entirely hides this with a smother of big flax flowers of white satin delicately veined with palest watery lilac.

On the north side of your mountain, in the cool, you may have a primula or two, especially P. pubescens Mrs. Wilson, a small neat auricula, very free flowering and cool strong lilac in colour; also P. Ruby, with intense ruby red flowers, and the old nivalis of gardens with snow white flower-heads and cowslip scented.

That must do for my list of plants for the ground floor. Now for a few to grow on the mountainsides, wedged in narrow crevices. Here we want small, compact-growing species to form tufts among the cliffs. A family that first comes to mind is saxifraga, and of these the kabschia section is especially good. S. Burseriana with its white flowers, huge and pure, on smooth red stems in earliest spring is lovely. Of all the yellow kabschias, S. Faldonside is still the best with its citron yellow blossoms, perfectly rounded; S. Irvingii, tiny, neat, thrifty, with hard cushions of close blue-grey foliage and countless little shell pink flowers; and S. Myra, larger flowered, but compact and dwarf, and rich cherry red. One more I must have, S. tombeanensis, later than the others and pure dead white in flower. These are the cream of a whole crowd of lovely species. Saxifraga oppositifolia you must have, with its shilling-big heather-purple flowers, stemless and brilliant in March. There are several varieties, and splendens is the best of them. Then S. Aizoon baldensis, the smallest of all the Aizoons, which Farrer and I discovered on the ridge of Monte Baldo. This is appropriate to the smallness of the sink garden, with its minute rosettes of encrusted silver and its white flowers on stems a couple of inches high. Last of the saxifrages, S. cochlearis minor, richly silvered in leaf, but with purest white flowers in sprays on red stems.

Here on the rocks are perfect homes for some of the androsaces, the grey felt pincushions of A. helvetica or the silky tufts of A. arachnoidea. Of campanulas I would choose C. Zoysii, for here it may hope to elude the wily slug, which thinks nothing of a four-mile tramp to enjoy a good tuck in at it. C. Zoysii flowers late in summer with pale lavender bells, all puckered together at the mouth like the smocking of a kalmia blossom.

Of pinks you have a choice of two or three, Dianthus neglectus, 3ins. high, with rose-pink flowers, buff yellow at the backs of the petals; or the minute D. musale, rare and dainty. Myosotis rupicola is a doll's house forget-me-not of dazzling azure an inch high. Wahlenbergia serpyllifolia is like a mat-forming campanula, which in May produces a crowd of big upturned bells of Tyrian purple. This has done uncommonly well in my sinks, and so, too, has its sister, W. pumilio, with starry flowers of lilac. I have named but a few of the plants one may grow in sink rock gardens, but, apart from telling of these favourites, I hope I have succeeded in suggesting the types of plants which are best and the best way of placing them.

HARDY ANNUALS

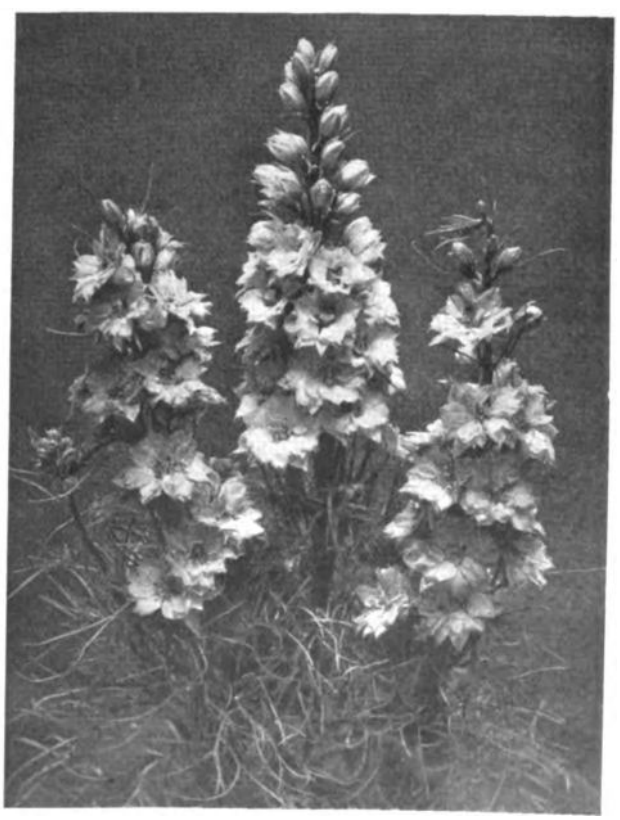
SOME NOVELTIES AND SPECIALITIES OF PARTICULAR MERIT.

THANKS to the arrival of seed catalogues, enthusiastic horticulturists have much to keep their minds busy even though the soil may for a brief period be quite unworkable, and as usual the novelty pages of the principal catalogues are brimful of good things, some of which, at any rate, should enter to considerable extent into our garden schemes for 1926.

There is reason to believe that the old-fashioned Scotch marigold (Calendula officinalis) in its up-to-date forms and varieties will figure very prominently in the coming season's floral pageant. We may thank an American horticulturist for concentrating attention upon the decorative capabilities of this flower, for it is largely due to the lead he gave us and to the introduction of the American variety, "Ball's" calendula, to florists' shops that we were led to realise the true value of the intense tangerine orange and beautifully regular double-flowered marigold we had so long neglected. An improved re-selection of Orange King and another fine novelty named Monarch, both of British production, are being distributed through the seed merchants by two of the leading seed growers, and both varieties are flowers of the richest colour imaginable, while their form is real perfection. One good point about calendulas is that they will grow in harsh soil, and even on sun-baked banks and terrace beds.

In candytufts the latest selections of both white spiral and white hyacinth flowered rank among the very best of white-flowered bedding plants. Many coloured candytufts are in cultivation, but few, if indeed any, can surpass the latest developments of Rose Cardinal, a variety of particularly bright colour which several firms have carefully re-selected until their stocks are remarkable for uniformity and brilliance.

Eschscholtzias are plants of the widest possible utility; their hardiness is something more than capability of germination in the open ground, for they will rough it in newly made gardens, in poor, stony soil, dry banks and open, windswept gardens. Several really distinct novelties in eschscholtzias are entitled to a cordial welcome, their habit being neater and more compact than that of older types, while they provide us with many new breaks in colour, some intensely brilliant, some soft and daintily bewitching, but all glittering with the sheen which is a distinctive characteristic of the genus. Robert Gardiner is the name of one newcomer which produces fine double flowers with fluted petals, the colour being a lovely, bright orange. Enchantress is another double, the outside



A MODERN STRAIN OF ANNUAL LARKSPUR.

of the petals being of a soft and pleasing rosy carmine, the inner part of the flower being of a paler, more delicate tone. A re-selected stock of erecta compacta Mikado which is being distributed among the trade this year is a decided advance upon the ordinary strains of Mikado to which we have been accustomed, and it may be remarked that in very many of

Digitized by Google

our most popular annuals the work of re-selection and refinement of standard varieties really gives us advantages equal to new varieties without the undesirable multiplication of names.

The new giant-flowered frilled dianthus which received the R.H.S. award of merit last year is a remarkably fine strain, producing broad, prettily crimped and fringed blossoms in bright rich colours and on long, stiff, wiry stems which facilitate artistic decoration in the house while holding the blossoms well above the soil and foliage to produce a fine effect in the garden.

Larkspurs are improving at a speed almost parallel to that of their cousins, the perennial delphiniums, and it is certainly to the credit of the annuals that the lovely pink of Exquisite and the still brighter shade of Rosy Scarlet give us clear, decisive colours which are yet a long way off in the perennial tribe. Violet Queen is a novelty of real interest, for it fixes a shade of soft restful colour which has hitherto been elusive in the extreme. It is the easiest thing possible to get variations in purples and the varied degrees of mauve, but few things are more difficult than fixing a particular shade, so prone are the colours to recede into dull plum or flat magenta purples. Larkspur Violet Queen will have a host of admirers. The new race of azalea-flowered godetias were quite recently eulogised in these columns, and it should be the endeavour of all who delight in gay, striking colour mixtures to secure seed and sow a pinch under cover as early as possible; while for a sheet of solid rich-toned crimson, Gloriosa, which received the R.H.S. award of merit, is the very thing. The plant grows compact and bushy to a height not exceeding a foot, and for many weeks in summer foliage is obliterated from view.

In clarkias, poppies, cornflowers and scabious there seems to be a general opinion among the producers that re-selection and refining the stocks of the best of recent years is of greater importance than setting up new names, and in that the trade will receive the general approval of the buyers.

In poppyland the Ryburgh double Shirleys and the re-selections of them by a number of good firms add glory and enchantment to the garden, and it is interesting to note that great progress is being made in fixing certain individual colours even in so fickle a flower as the Shirley poppy so that seeds can be offered with satisfactory prospect of securing quite a good proportion of seedlings true to a particular colour.

More of outstanding merit awaits attention in novelties among half-hardy annuals, but they must form the subject of a further article. A. J. MACSELF.

PLANTS TO RAISE FROM SEED

IN THIS ARTICLE IS GIVEN A LIST OF A FEW NOTABLE PERENNIALS WHICH SHOULD BE SOWN DURING THE NEXT FEW WEEKS TO ENSURE A FINE DISPLAY THROUGHOUT THE SUMMER MONTHS.

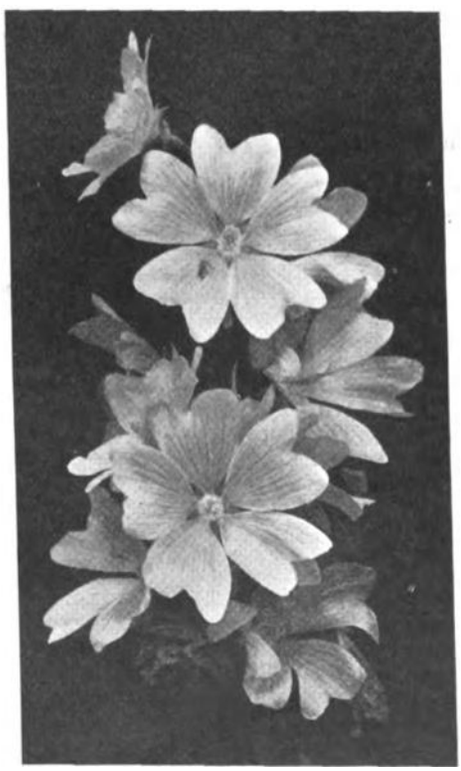
IT is the present-day gardener's good fortune to be able to secure through the trade lists seeds of many fine perennial plants which were at one time difficult to acquire through any but a private source. This, perhaps, applies to perennials even more than it does to annuals, and in alluding here to the former I could hardly do better than take at random from seed lists before me a few names by way of indicating the wide variety of these subjects, other than alpines, which are now procurable from the trade catalogues in the form of seed.

How often, I wonder, has seed ever been offered of that beautiful Madeiran geranium, G. anemonæfolium? Yet here it is at sixpence per packet, thus placing within reach of everyone a superb species which is easily raised by outdoor sowing, quite hardy enough for most places and which, throughout the summer, will produce masses of large, clear pink, ruby-eyed flowers above the great, hemlock-like foliage.

Then there are the aquilegias, which include not only the better known kinds of the border but such choice species as AA. alpina, Reuteri, canadensis, glandulosa, flabellata and the lovely cœrulea. There is no difficulty whatsoever with any of these, and whether one is stocking a rock garden or has wide woodland spaces to fill, a batch of sturdy seedlings is a very gratifying possession.

Ranunculus graminifolius catches my eye, and I can visualise a goodly patch of this elegant species near the water, its silvery, grassy leaves making a most attractive setting for the big, glistening golden flowers. There is seed of others also offered in quite cheap packets: the noble R. creticus, for example, and R. amplexicaulis, so pale and cool in blue-green and white.

Few things are more easily produced from seed than the beautiful Sparaxis pulcherrima, and there is nothing which responds more heartily to this treatment. Put out in their permanent positions while quite young, seedlings of this eminently graceful plant always seem



THE HANDSOME LAVATERA OLBIA.

to be more successful than older specimens, and the seed of most of the choice varieties can be relied upon to come fairly true. The shaggy-headed Aster Farreri, until recently a novelty, is now procurable in a seed packet, as are such other species as sub-cœruleus, diplostephioides and yunnanensis. Where once you could rarely secure seed of any of the more uncommon flaxes, such excellent species as Linum monogynum, L. alpina and the yellow-flowered kinds are now listed. L. monogynum is a robust perennial which should always be raised from seed sown where the plants are to grow. In waving masses its elegant, emerald green, leafy stems, crowned all summer with large milk white blooms, can be most delightful.

Papaver pilosum is a perennial which deserves to enjoy a much wider popularity, with its branching stems and showers of splendid flowers of a fulvous orange, and rising to a height of 2ft. This is just the thing for massing on dry slopes or in open woodland, and a nimble ninepence invested in seed will yield any number of plants. Then, there is that irresistible dainty, P. alpina, and lovely nudicaule, whose names I may risk mentioning without being drawn into the thronging world of alpines. The perennial poppyworts also claim notice, and among the best which come readily from seed with me are Chelidonium (Dichranostigma) Franchetianum, glaucous of leaf and very charming in its prettily crimped big yellow blossoms; Stylophorum diphyllum, a 2ft. woodlander of even greater distinction; the milk white Sanguinaria canadensis, and the best perennial meconopsis. Regarding these latter, I must add that we are now able to get seed not only of such beautiful species as MM. latifolia and simplicifolia, but the rare, costly and exquisite M. quintuplinervia is already available in seed packets.

Lavatera Olbia, a few years ago not easy to get true even as a plant, can to-day be obtained per the seed packet, and a nobler subject of its character never graced our borders and woodlands. In pentstemon species (including Chelone) seed is procurable of a dozen distinct and handsome kinds, and few plants can be more readily raised by such means. No less can be said of the alliums, of which we are now able to acquire, *via* the

Digitized by Google

SANGUINARIA CANADENSIS.

seedsman, such notable kinds as the towering A. Rosenbachianum in rosy lilac, the glorious A. narcissiflorum and

THE SHAGGY-HEADED ASTER FARRERI.

little A. cyaneum, so chaste and demure with its nodding heads of blue. But this allusion to the onion race reminds me that I am steering perilously near the shoals of innumerable bulbous things. So to the safer country of the campanulas, of which will be found in any good seed list a range of well tried favourites and novelties not a few, from the 3in. C. Bellardi Miranda to the latest thing in C. macrantha standing at 5ft.

Digitalis ambigua is a very delightful woodland perennial which comes true from seed, and an informal group of this, with Borago laxifolia trailing about with its delicate azure bells, together make a most telling yet refined combination. Gaura Lindheimeri, a tall and graceful relation of the evening primroses, is offered in the seed catalogues and might be more often seen, and the same remark applies to the old acanthus-like Morina longifolia, and to Francoa ramosa, which latter I have found hardy enough to laugh at twenty degrees of frost. The thalictrums, from the rare yellow and lilac T. Chelidonii of 6ins. to T. dipterocarpum of as many feet, can also be included in one's seed order. With the lupin-like Thermopsis montana and others brought up from seed I have had pleasant associations, nor can one omit to mention the Caucasian scabious (always best when introduced from the packet), of which there are now so many lovely forms in infinite shades of deepest blue, approaching violet, to the most delicate lavender and white.

Then, by way of pointing out the extent of one's choice in seeds, even if it is not in common parlance a "perennial," there is that exasperating enchanter, Tropæolum speciosum. And I have not much doubt that, if those who have had difficulty in establishing the flame flower were to try it from seed, they would quickly realise their ambitions. A notable newcomer which the up-to-date seedsman puts within reach of everyone is Lupinus

THE TALL BLUE AND WHITE SPIKES OF SALVIA DICHROA.

Paynei, a tree lupin of 6ft. and most graceful proportions, which is wreathed in rosy lilac to rose pink blossoms the season through. I have found this Mexican quite hardy, and it will often flower in its first year from seed. Salvia dichroa, with its great mullein-like leaves and tall spires of blue and white, is another uncommon and splendid perennial whose seed will germinate freely, grow away with the heartiest vigour and live for ever.

A. T. JOHNSON.

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information available from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2.

NOTES OF THE WEEK

THE DAISY BUSH AS A TUB PLANT.

A VERY effective plant for ornamental tubs is to be found in the daisy bush (Olearia Haastii). This New Zealand shrub forms a dense and extremely neat bush from 2ft. to 4ft. high. The small, round leaves are thick and very much resemble the foliage of box, apart from the fact that they are larger and of a brighter green. White daisy-like flowers are produced in great abundance and are borne in such broad clusters that the whole plant appears to be covered with bloom. The daisy bush starts flowering early in August and presents a fine spectacle for quite a month. The soil in which the olearia is planted should be on the light side and perfect drainage is essential. Given such conditions a small specimen will rapidly grow to a good size. The daisy bush is easily increased by means of cuttings of half-ripened shoots struck under a bell-glass in a little heat. Another method of increase is to be found in making layers of the plant in the autumn. Specimens of the daisy bush in tubs usually keep a good shape, but, when any trimming is required, this should be carried out in the autumn.—S. LEONARD BASTIN.

A DWARF CHERRY (PRUNUS INCISA).

FIVE years ago I searched in vain for this cherry—none of the Japanese, Continental or English nurserymen seemed to stock it, and it was only by the merest of chances that I finally discovered it growing, of all places, in a remote corner of Ireland. It happened in this wise: One of the specimens in the Kew collection had on its label the legend "Somebody's Seedling." It was not, of course, difficult to find where the said "Somebody" lived, and I soon enlightened him upon the identity of his "seedling" and ultimately acquired several fair-sized plants from him. Lately Prunus incisa has crept into several catalogues, and when the merits of this sturdy little cherry are better known it is safe to prophesy that every self-respecting nurseryman will be offering it for sale, for this is a valuable plant, particularly when lack of space prevents larger-growing flowering cherries from being used. With me it thrives in shade or sunshine, and in the early spring is so extraordinarily liberal with its white flowers that it holds a very high place in my affections. As all my plants appear to have been raised from seed the quality of the blossom varies somewhat, and in this respect one specimen is vastly superior to its fellows. It grows wild on the slopes of Fujiyama, and, being a mountaineer, it possesses a very hardy and tough constitution, which is also greatly in its favour. The Japanese call it Mame-Zakura—meaning pigmy or dwarf cherry—but whether they so name it because of its diminutive stature—for at best it is only a small tree—or because it is the species they most frequently use for dwarfing purposes, I am unable to say. Its deeply cut, birch-like leaves and neat habit make it an attractive plant, whether in flower or foliage.—COLLINGWOOD INGRAM.

THE PIGMY CHERRY, PRUNUS INCISA.

GYPSOPHILA ACUTIFOLIA.

NONE of the gypsophilas, or chalk plants, can hope to vie in popularity with that general favourite, G. paniculata, and its double variety. They are excellent both in the garden and for cutting purposes. Even admitting this, however, there is surely room in the garden for another tall species, and notice may be directed to G. acutifolia, one very little cultivated, but procurable in plants or seeds. It is taller than G. paniculata, being 3ft.—and more at times—in height. It has glaucous, sharp-pointed leaves and panicles of small pink flowers. These are larger than those of G. paniculata, but much more sparsely borne, and therein lies the secret of why G. acutifolia compares unfavourably with its ally. I have grown G. acutifolia in a dry border and have found it quite hardy and calling for no special treatment. It requires staking, however. Seeds are obtainable from a few firms specialising in hardy flowers, and may be sown under glass in spring. A sunny position in light, well drained soil is the best for G. acutifolia.—S. A.

THE PROSTRATE ROSEMARY.

FEW who are putting in rock garden shrubs can afford to overlook the merits of the dwarf and prostrate form of the common rosemary known as Rosmarinus prostrata. Coming as it does from the cliffs of the Isle of Capri, this delightful shrub is not quite hardy everywhere. It is, in fact, more tender than the type. Even so, it is a subject of such singular charm, so manifestly a rock shrub by nature and in habit, that it is well worth while anyone's risking a plant or two, especially as it is not expensive. Moreover, R. prostrata, as it rambles about, hugs the ground or rock face so closely that it can be protected simply by laying a few evergreen branches over it during frosty weather.

R. prostrata is a pleasing feature in the rock garden even in winter, for whenever conditions allow it to remain uncovered (it withstands 10-12 degrees of frost with me), its lively green and elegant manner of growth are extremely attractive. Quite early in spring its pale blue flowers appear. These are produced in the utmost profusion and, as often as not, there is a second crop in autumn. We find this little shrub does admirably in the poorest of very dull and stony soil, and in such a medium the chances of its getting safely through the winter are much in its favour.—N. WALES.

ŒNOTHERA MARGINATA.

THIS beautiful species is not often seen in gardens, even where it would undoubtedly do well. It is certainly not as reliable as some of the large-flowered, dwarfer evening primrose, having a way of disappearing after a season or two, unless the soil and situation are exactly to its liking. Albeit, Œ. marginata is such a lovely thing, quite the finest, I think, of its class, that it is well worth a trial wherever conditions seem congenial. Those conditions are not exacting, for a loose, sandy or stony, warm soil with, say, a westerly aspect, seems to suit it admirably.

Œ. marginata has an entirely different habit from that of missouriensis, taraxacifolia and others of the big-flowered set, for, instead of making annual trailing stems, it runs underground, putting-up at intervals a bold rosette of long, narrow leaves of a silvery pale green, slightly toothed towards the base and often having the mid-rib tinged with red. The blossoms, borne on comparatively short stalks, are larger than those of any other œnothera known to me. That is, they are often fully 6ins. across, of a most immaculate, glistening whiteness and the perfume is delicious and suggestive of that of a magnolia. As the blooms die off they turn a soft carnation pink.

Since this charming species does not resent moving, rooted tufts may be lifted in autumn, potted-up and kept in a cold frame where there is any risk of winter loss. Put out in spring such plants will soon increase and blossom the following autumn, if not earlier.—A. T. J.

RAMONDIAS AND HABERLEAS.

ON several trips in the Balkans I have paid special attention to the two fine and rather rare members of the gesneraceæ whose home is in that corner of Europe—ramondia and haberlea. I went to Nish in Serbia late in the spring, and started as soon as possible for the Suha Planina, a fine mountain a few hours to the east of the town. Almost at its foot Ramondia Nathaliæ is to be found. Here it grows on shady moist rocks, covering the stones with the tufts of broad ovate leaves, which are clearly shown in the illustration. The plants were not yet in bloom at this time of the year, and I was sorry to miss the beauty of the deep violet flowers. The colour of the flowers is not yellow as is sometimes stated; there is only a golden eye in the centre.

Ramondia Nathaliæ is often described as a mere variety of R. serbica, another species met with in south-eastern Serbia. As a whole, the latter is a less ornamental species with narrower, almost spathulate leaves, and more campanulate flowers, which are usually five-lobed, while those of R. Nathaliæ have normally four. The oldest and best known species of the genus is R. pyrenaica from the Pyrenees, with a rotate five-parted corolla of a purple-violet colour. There is a good white variety, var. alba, and a less conspicuous var. rosea.

The second genus I met with on the Balkan Mountains known as Stara Planina was haberlea. I also found it near the little village of Kalofer not far from Kasanlik, the well known locality where the rose-oil comes from. On the southern slopes of the Midzur, haberlea can be found in the same situations as ramondia in Serbia. Besides Haberlea rhodopensis, only one other species of this genus is so far known, H. Ferdinandi-Coburgi. Both are rather alike, and differ a good deal from the allied genus ramondia. The differences between leaves and flowers are well marked in the illustration. The flowers of haberlea are distinctly tubular, somewhat reminiscent of little gloxinias. The colour is a pale bluish violet, deeper in the tube.

These are, indeed, precious plants for shady and moist parts of the rock garden. Their cultivation is by no means difficult, although it is no easy task to establish good plants. They can be raised from seed without any difficulty. It is best to sow the seeds shortly after they have fully ripened, but they usually do not germinate before spring. The seeds are very small, and ought to be treated like those of Primula rosea or P. auricula. The young plants are grown in pots and kept in cold frames until the second spring. Then they can be planted in the rock garden between or on almost vertically placed stones near some running water. Count Herbert Schaffgotsch, who has established fine colonies of those plants in his rockery at Purgstall, Lower Austria, advises people to put the plants against a flat stone covered with a layer (half an inch) of peat and a little loam, to spread the roots flat on this soil, and to cover them again with another layer of the same material. Then flat stones should be placed round the plants to keep them in their position. Well-established plants flower very freely, usually at the end of May or beginning of June.—CAMILLO SCHNEIDER.

THE DAINTY ALMOST GLOXINIA LIKE FLOWERS OF HABERLEA RHODOPENSIS.

RAMONDIA NATHALIÆ. A RARE GEM FOR THE ROCK GARDEN

DAPHNE MEZEREUM.

THIS doubtful native of our country is a great favourite with all; but, with few exceptions, it is the cottager who grows it most successfully. In February or March it may often be seen in small gardens standing up among the dwarf spring flowers like a miniature tree, the sparse branches literally smothered with the purple or lilac blossoms. The cottager's plants are always seedlings, and it is not until later that they assume the bush-like habit. Large plants are not common anywhere. Often this is due to disturbance of the roots, change of ownership, and sometimes to a distressing habit, from which even seedlings are not quite exempt, of dying when they have attained any size. A good bush may have as many as seventy to a hundred branchlets.

Why is this daphne so scarce in our larger gardens? Is it because *grafted* plants are usually purchased and planted? Twenty years ago I purchased and planted many such plants, only to see them die in a few years. Anxious to repair the losses sustained, I obtained as many berries as possible, sowing them in large pots, with ample drainage, as soon as ripe. A few germinated the next spring, and many more from the same pots in the following spring. Unfortunately, they are rather slow in growth at first, and it was quite four years before they were large enough to plant out; but they make up for it afterwards. Just when the grafted plant begins to wane, the seedlings wax vigorous. The colours of the seedlings vary slightly from pale to reddish purple, but this is an advantage, providing variety if the plants are used singly and a charming harmony of colour when they are massed. A colony of the seedlings raised as described has been very beautiful here for the past fifteen years. Unfortunately, they were planted too thickly, and the more central plants are beginning to show signs of distress. Here I would plead for sufficient space for each plant to develop. Five feet apart is a very bare allowance, and should be given them when first planted, as when established they resent disturbance. The bare earth can be easily covered with some spring flowering plant, such as aubrietia, arabis, or the paler shades of Munstead polyanthus. It is possible to raise the white-flowered Mezereon true from seed, but the colour bears no comparison to the purity of that known as Paul's White; but the plants, being necessarily grafted, are very short-lived with us.—J. COMBER, *Nymans Gardens*.

ON THE ARBUTUS—WITH SOME DIGRESSIONS

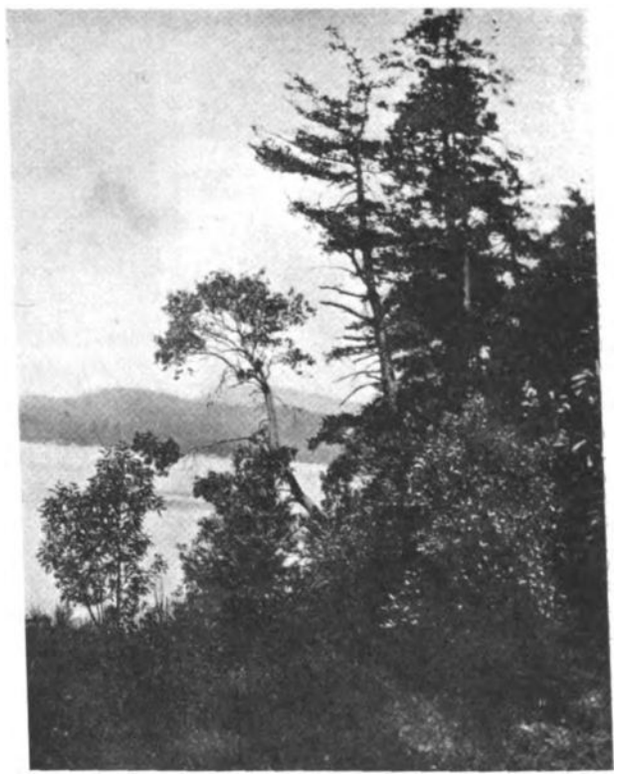
BY THE LADY BYNG OF VIMY.

MR. BEAN'S interesting appeal for the arbutus family in THE GARDEN of October 31st, 1925, comes at a moment when my mind, happening to be rather full of these particular plants, makes me feel I must rush into print on this subject.

Arbutus Menziesii is not only Californian, but grows profusely on Vancouver Island, B.C. All along the coast, beside the lakes, and always facing the full sun as though it had a feminine vanity in knowing its beauty was enhanced by careful choice of a setting. There are few things more wonderful than A. Menziesii, clinging to the steep slopes of Malahat Pass, high above the deep gorges filled by tidal waters, with a cloudless sky overhead and in the distance Mount Baker, snow-capped and serene, silhouetted against the crystal-clear atmosphere that is one of Canada's most salient features. Away up the Island, nearly as far as Campbell River, the arbutus thrives. But I have specially in mind a small peninsula, near Saanich, on which the Lieutenant-Governor of British Columbia is building himself a summer cottage of fragrant cedar wood, with massive stone chimneys, and wooden "shingles" stained to recall weather-worn thatch. But it is the arbutus that are the outstanding feature of that peninsula, which is thrust out into the Pacific Ocean, and where on the one side the water is ice-cold, on the other warm and serene, as little waves come lip-lapping against its sandy beach, fringed with those quaintly twisted, terra-cotta stemmed arbutus trees, overhanging, in all manner of strange angles, the aqua-marine water and outlined against a cerulean sky. They make of the spot something between the fairyland of one's dreams and the dainty reality of a Rackham drawing, that lives in my memory and calls up a scent of hot pine needles and sea, two of Nature's best perfumes. In England we shall, I fear, never grow Arbutus Menziesii like this; still, it is worth trying, as I tried this summer when, with infinite care, my gardener and I lifted small plants. They are confessedly difficult to shift, but we took very small trees, gave them all possible care, both in lifting and packing for Thorpe—but every single one "went West." It was later on, during a train trip in the Island, that I heard of a trick for transplanting these treasures. The superintendent of the little line told me that a friend of his, who had always previously failed in lifting the plants, adopted the following method: The tree was lifted carefully, planted in a box or the open ground, and bent over till it lay along the soil into which the tips were plunged, and from the plunged end came roots and a small tree formed. He never lost a single one since adopting this method! Certainly it would not have crossed my mind to try such an experiment, and I wonder if any of your readers have done so.

In the same article on the arbutus, Mr. Bean refers to the Unedo or strawberry tree, and here I can give an instance of its amazing vitality that may be thought apocryphal, but which, nevertheless, is true, and, were I not more than three thousand miles away I could send you a photograph to verify the following story.

In 1914, when we first went to Thorpe-le-Soken, I found several bushes of Unedo about the place, and a very large one



ARBUTUS MENZIESII GROWING WILD.

hemmed in among masses of laurel and kindred rubbish, dear to the mid-Victorian gardener's heart. The poor thing was lop-sided, misshapen and, unfortunately, placed on the top of a bank where necessity forced me to scrap it. Down it came, ruthlessly chopped and hacked, a ruin of such dimensions that to remove it would have entailed a great deal more time and labour than I could afford, so I rolled it down the bank on the top of which it had been growing, meaning eventually to plant an Albéric Barbier rose over it as a shroud. Then came the war, and there was no rose planting—potatoes and vegetables of all kinds filling the gardening calendar. But so unsightly was the Unedo stump that I flung a handful of nasturtium seeds round it, and during the summer of 1915 it was gay with gold and crimson flowers. That autumn, as I poked round the bank, I found some small, healthy-looking shoots coming up from the base of the sawn-off limbs, but thought them a last flicker of sap remaining in the moribund stump and left them alone. Next year more shoots appeared, and so it continued, all these shoots thriving, till now, nearly eleven years after the execution, I have a splendid bush of Unedo on the bank! What evidently happened was, that on rolling the stump down it fell on its base, and the bank, being gravelly and gritty, set up root action, and so the arbutus has survived, having evidently a very different temperament and constitution from its cousin of the Pacific Coast.

But the words Pacific Coast take me back again where I started—to Canada and its flowers and to that peninsula which I saw on a grillingly hot August day, when the grass was scorched a crackly buff-brown, its surface as slippery as ice. The peninsula was a steep hillock, thickly wooded with cedars, hemlock, spruce and madrones, while through the burnt-up grass stood dodecatheon stems with their golden brown seed-pods, tall seed heads of pink and white erythroniums, fritillaries and Lilium Columbianum. Thickets of "fairy roses" with their tiny leaves and equally tiny hips

WILD FLOWER LAND IN THE ROCKIES.

Digitized by Google

covered spaces where the sun penetrated, while blue-mauve brodiæas, minor and grandiflora, spread themselves in big patches, and the heavy heads of pink and white alliums nodded in the breeze. And all this was native; there was no cultivation, nothing but Canada's wildings in their natural state. Could any gardener wish to improve on such a succession of bloom? Could any man have chosen a more entrancing spot for a summer retreat?

But it is not only in such corners as this that Canada shows her floral wares. There are endless places that come to my mind as I write. Jasper Park, for instance, that 4,400 square miles of forest reserve, where porcupines, bears—grizzly, cinnamon and black—deer, mountain sheep and goats, and all the other wild beasts wander free and tame because no man's hand may be lifted against them and where flowers abound in undreamt of masses; the railway banks dyed orange-scarlet with Lilium philadelphicum, while Cypripediums montanum, parviflorum and candidum nestle in damp, mossy corners, the purple and white showy orchis carpets in spring—certain favoured dells that I will not betray lest tourists rifle them—and the woods in early autumn are gay with the scarlet berries of the twisted-stalk (Streptopus roseus), false spikenard (Smilacina racemosa), fairy bells (Diosporum trachycarpum), red baneberry (Actæa rubra), while the quaint white doll's eyes (Actæa alba) and the rich blue of the Clintonia borealis form a wonderful contrast to the crimsons above them. In open spaces during late summer the pallid beauty of Zygadenus elegans lifts up its creamy bloom heads and spear-like foliage, and the silver-grey rosettes of the oxytropes form an admirable setting for the vivid purple flower-spikes. In spring the damp "flats" along the Athabasca River are starred with dodecatheons, violets and countless other treasures that it has not been my good fortune to see. Not only in Jasper do flowers abound, but also back again to Vancouver Island, round lakes like Cowichan, with its inrushing rivers, its wooded mountains and rocks, where I scraped and dug, ruining pick and spade, in the search for liliums and erythroniums, saxifrages, sedums, dodecatheons, and in the woods Calypso borealis, as well as tiny ferns wedged tightly between the rocks. In the water I found a yellow water lily, shaded externally with flame and orange, that I have never seen elsewhere, and have sent to Essex in the hope that it will thrive. I know of stony, summer-dried river beds there where alpines get washed down by the spring freshets, tiny plants marooned among the stones or on the banks, and which the collector can gather without the effort of clambering to snow line, though he will ruin his boots against the river-bed stones, break his finger-nails and his temper too in digging. There are stretches on the prairies carpeted with the Anemone occidentalis, orange-red creeping mallows, and the dainty plumes of Geum trifolium, while the silver-green eleagnus bushes break the level of the "bald-headed prairie" with its all-prevailing tufts of sage brush and "sloughs" of startlingly blue water, alive with wild duck. Erodiums there are in quantities, of a richer tint than we get at home. Camassias thrive in the west and all kinds of rubus spread themselves both east and west, as do the Linnæa borealis, the pyrolas and other woodland treasures, while throughout British Columbia the Fatsia horrida in the dense woodlands uplifts huge heads of flaming scarlet berries that glow like the torches of some mediæval procession.

PLUMS AND CHERRIES

(*Continued from page 56.*)

PESTS.

PESTS, especially aphides, have been known to check the trees severely by damaging the foliage, and thus preventing the proper functions of bud development. It is not an uncommon sight to see the leaves of plum and cherry trees badly curled and distorted through aphis attack. Control measures against this pest and others should be commenced during winter.

On standard trees grease bands should be applied for trapping the females of winter moths. In addition, these trees and others ought to be sprayed during the most dormant period, December to February, with one of the excellent tar-distillate washes for the purpose of destroying the eggs of various insects. The value of these washes to the fruit grower cannot be over-estimated. They are of comparatively recent introduction and provide a distinct advance on anything I know for the cleansing of fruit trees of pests in winter. It is not claimed that this winter washing will ensure the freedom of the trees from pests during the following summer, but it will go a long way towards it.

A watch should be kept for the leaf-curling aphis and, should any appear, measures must be taken to combat it at once. If left these pests increase at an alarming rate and the leaves rapidly curl up. A nicotine and soft soap spray is the most effective remedy.

The plum is liable to be attacked by several diseases, notably the baffling silver leaf disease, which has caused the death of thousands of trees. There is no known reliable cure for this disease, and it is best to remove any branch after fruiting which shows signs of the silvering. The cut surface should be immediately covered over with Stockholm tar and the branch burnt.

The disease known as black rot which attacks apples, may also affect the plum, also the related diseases known as wither tip and blossom wilt. Some varieties are apparently more subject to attack than others. We have observed this with the variety, Grand Duke, more than any other. Affected trees are recognised by the withered tips of twigs which remain on trees throughout the winter. These diseases are difficult to control by spraying, but all affected shoots should be removed, also any fruits showing signs of brown rot.

In early spring, just before buds burst, it is advisable to spray with strong lime-sulphur.

MANURING.

Manuring is generally only necessary when trees are carrying, or have carried, heavy crops of fruit. A top-dressing of farmyard manure, with the addition of artificial fertilisers, is best.

Basic slag and kainit can be applied in autumn, at the rate of 3 oz. or 4 oz. of each to the square yard, or superphosphate and sulphate of potash in spring, giving about 3 oz. of the former to 2 oz. of the latter per square yard.

A nitrogenous manure may be necessary, unless this is supplied in sufficient quantity in the animal manure. If an artificial is applied this can be given after the fruit has set. For heavy soils nitrate of lime is useful, though nitrate of soda or sulphate of ammonia will meet the case, either must be given in moderation, 1 oz. to the square yard being sufficient. The object of the nitrogen is to maintain healthy foliage, and should the latter have a pale or sickly appearance, a small dressing will often work wonders, unless, of course, the unhealthy appearance is caused by such as bad drainage.

VARIETIES.

There are so many varieties of plums and gages that it is difficult to select half a dozen without feeling that others almost, if not quite as good, have been left out.

Rivers' Early Prolific, though classed as a culinary, is well worth including, owing to its earliness and all-round qualities. It flowers early and is only partly self-fertile, so must have the association of other varieties to assist in pollination.

The Czar is a reliable companion, and one of the best croppers, though not a dessert variety.

As a dessert gage few can surpass, if equal, Denniston's Superb, which has the advantage of being self-fertile. The several transparent gages are all good, as are Jefferson's and Allgrove's Superb. Victoria is always popular and the same applies to the old greengage. As a late variety Coe's Golden Drop is a favourite.

CHERRIES.

Cherries are exceedingly popular, but in many ways present more difficulty in culture than other fruits. They seem particularly fastidious as to soil and even when a mixture which they are supposed to enjoy has been added to the natural soil of the garden, they do not always succeed. The ripe fruits are more tempting to birds than probably any

Digitized by Google

other, and unless protected from them they often take a heavy toll. Again, rain during the ripening process frequently causes the fruits to split.

The general management of the sweet cherry does not differ in many respects from that of the plum. It is most successfully grown in chalky districts, such as is found in some parts of Oxon and Bucks. Stiff soil should be avoided. It enjoys sandy loam over chalk. A good depth of soil is necessary, as the trees require a lot of moisture. The method of planting is the same as for the plum, and a similar mixture, with the addition of chalk, is to be recommended.

The trees should not be pruned the first year after planting, owing to the danger of gumming, and as a matter of fact the cherry requires very little pruning at any time. What pruning is done should mainly take the form of summer pinching back of young shoots. In the case of bearing trees, this is best done as fruit is colouring. The cherry tree, like the plum, is easily managed as a standard, and after the six main branches are formed it is seldom necessary or advisable to prune the leaders.

This to a very great extent is applicable to the trained trees on walls or fences, and the bush tree grown in the open. For low fences or walls up to 6ft. the espalier-trained tree is best, while the fan-shape is to be recommended where height allows for development; at least 15ft., and preferably 20ft. in width, should be allowed whichever shape is chosen.

The Morello cherry is treated quite differently, as regards training and pruning, from the sweet varieties. The latter fruits on spurs which are formed along the branches. The Morello fruits on wood of the previous summer's growth in the same way as the peach. It is almost invariably trained as a fan and planted against a north wall, where it is known to succeed admirably. Essential cultural points are the laying in of a good foundation of main branches, from which are produced the fruiting shoots for the following year. After the crop has been gathered these shoots are cut out, and young growths made during the season tied in to take their places. Overcrowding must be avoided; this can be done by training the somewhat slender shoots about 3ins. or 4ins. apart.

A point of importance in the culture of plums and cherries is to avoid forking deeply around the trees. Such a practice would do infinite harm to the fine fibrous roots which are generally to be found near the surface.

A few good varieties of sweet cherries, suitable for gardens, are: Waterloo, Noir de Guben, Governor Wood, Frogmore Bigarreau, Noble, Early Rivers, and Elton. ARTHUR J. COBB.

PLEASE REMEMBER TO TELL OTHERS ABOUT YOUR PLANTS THROUGH THE COLUMNS OF "THE GARDEN."

CORRESPONDENCE

PIERIS IN SCOTLAND.

SIR,—In the issue of THE GARDEN of January 16th "E. H. M. C." asks for some information regarding the cultural requirements of Pieris floribunda. From what he says it appears that he has been rather unsuccessful with them. He seems to be in doubt, however, whether it has been unsuitable conditions, soil, etc., or severe frosts that have crippled his plants. We have a very considerable collection of rare shrubs here, Pieris floribunda and P. variegata being among them (and which are all under my charge). With the pieris family we have found no difficulty at all in their cultivation, not even requiring protection from frost. In this part of Scotland we experience very severe winter weather and, worst of all, very early autumn frosts and late spring frosts, which are most detrimental to young growths of flowering shrubs.

The method we have followed here when planting pieris has been to take out holes two or three times the size of the plant roots. We have a compost made up of about equal parts of half-rotted leaves, fibrous peat and rough sharp sand. Beneath the plants and all round them this compost is firmly packed, with some of the natural soil mixed with it, and we find this mixture suits the plants well. They are vigorous and healthy, and flower most abundantly. The plants have a south-west aspect and are situated not far from a wall. They are well protected from east winds and partly so from north winds. This winter these plants have been exposed to 26 degrees of frost on December 24th without any protection (and 30 degrees on grass). For weeks the thermometer never fell below 10 degrees, oscillating from that to 18 degrees every other day. Our plants have come through this very severe trial with no protection whatever, and they show not the slightest ill effect. Seedling pieris appear to do badly also with "E. H. M. C." I increase the stock from cuttings of partly ripened wood.—WM. GRANT, *The Gardens, Crathes Castle, Kincardineshire.*

FREESIAS.

SIR,—I noticed the Rev. J. Jacob suggests soaking freesia seeds. I have not found this necessary, a packet of seed giving me six pots of seven seeds each. These were sown in September, 1924, placed on a shelf of a cool house, and removed to another house during the first week of January with a small heating apparatus giving a temperature of about 45 degrees.

The first blooms were obtained during the second week of February, while the last bloom, of a lovely violet colour with a rich yellow blotch in throat, was cut April 23rd, 1925. As each pot finished blooming it was taken back into the cold house again and given no water. Seeing it was so easy to raise from seed and much more interesting, I decided to throw the corms away, which I did during May, among some rank-growing grass where nothing else will grow; no sun ever shines there. During August I saw two corms lying on the ground. Examining them I saw they had started to sprout. I searched among the grass for more bulbs and found enough to fill two pots with seven bulbs each. These I placed under a greenhouse shelf, and were treated the same as seeds, with this exception, that they were removed to a warmer house at the end of November, in the hopes of flowers for Christmas. I missed this by a few days.

Unfortunately, during the last two Decembers I have been laid up, and the freesias, through an oversight, had no water for nearly the whole of that time. If they had I feel sure I should have succeeded with seedlings within six months and the bulbs for Christmas.

My seedlings for this year, I am afraid, are a failure through lack of water and attention. When I saw them on January 4th, 1926, the first time since the end of November, the grass was over the pots and not a good colour.—T.

A GOOD EVERGREEN SHRUB.

SIR,—Many shrubs for winter foliage or bloom have been mentioned in your columns during the past few months, but one which embodies both of the foregoing requisites seems to have been overlooked.

The shrub I have in mind, although I am not certain this name is correct, is Othonna denticulata. It is well furnished, evergreen, with heath-like foliage of a light green colour. The yellow blooms are individually insignificant, but are borne in large numbers, the combined effect of bloom and foliage being delightful.

It has a very neat habit and is easily struck from cuttings taken in the early autumn; several in my garden, struck in the autumn of 1923, are now splendid rounded bushes 3ft. high, carrying masses of bloom from November to March; while some bloom may be seen on them during any month of the year. For foliage alone this shrub is well worthy of a place in the choice shrubbery.—P. E. E. C., *Cornwall.*

TREE AND SHRUB PLANTING AND ITS ASSOCIATIONS.

SIR,—In your editorial remarks in the number of January 9th you express some surprise that the older garden enthusiasts come to prefer trees and shrubs and such like comparatively slow-growing subjects.

As one of the older race, may I be allowed to give a reason for this development of taste. I can imagine a garden lover arriving at this ideal from varying standpoints, but all arrive in the end at somewhat the same development.

Take the case of the man who builds a house and plants the garden for himself. If there are no trees or shrubs on the ground, he wishes to plant some to clothe his dwelling in time to shelter it from the wind and, possibly, from the prying eyes of others; and, having made his garden and observed defects even with the best thought out scheme, he wishes to improve it and to leave some record of his having been there. What finer record can he leave than well planted surroundings? Nothing except trees will give this. He knows he will soon be forgotten, but hopes that his name may be associated with some exceptional tree. You have mentioned the oak: how many names of men are remembered by some oak tree that still bears their name?

An alternative case is that of the man who acquires or inherits a house with grounds wisely planted; he is grateful to those who preceded him, for their good deeds as gardeners or foresters have given him much enjoyment. The trees may be mature, and the winds will take their toll of them; but he can show his gratitude by handing on the grounds to his successor at least as well planted, if possible increased in interest by adding a well considered selection of the more modern introductions. Few of us can hope to see a tree we plant ourselves reach maturity; but, having benefited by the planting of past generations, we can get satisfaction by knowing others will obtain pleasure from what we hand on to those who follow. As a man grows older he realises that he cannot get quick results and leave his mark behind him; and with advancing years time hurries past so quickly that the

Digitized by Google

slow growth is not irksome. Rather one wonders at the progress made in a few short years.

We in Scotland still read the Waverley Novels at times, and most gardeners remember the advice given to the Laird of Dumbiedykes: "Aye be pittin' in a tree, Dumbie; it will be growin' when ye are sleepin'."—WILLIAM LOW. *Balmaketwan, Marykirk.*

THE TALLER CAMPANULAS.

SIR,—In connection with the recent notes in the pages of THE GARDEN under the above heading, I would like to add my appreciation of the bellflowers to that of your contributors "T. W. B." and E. A. Ladhams as subjects eminently suited for border planting. I enclose a photograph of one of the taller species planted out in the border, and your readers will readily realise their value where

EFFECTIVE BORDER PLANTING WITH THE TALL CAMPANULAS

it is desired to furnish a bright display of one particular plant. They accommodate themselves readily to many positions in the garden, but, in my opinion, they are rarely seen to better advantage than when planted in the mass and in such a position as is shown, more especially when backed by a shrubby background.—H. C.

CONVOLVULUS MAURITANICUS.

SIR,—I fully agree with the writer of the article on "Annuals for Hanging Baskets" (THE GARDEN, January 16th) as to the charms of Convolvulus mauritanicus, but he is mistaken in thinking it an annual. It is a perennial and, although easily raised from seed, I have not found it a quicker grower, but, on the contrary, rather slow in reaching the flowering stage. It is not very hardy in my garden, and of the many plants I have raised from seed only one remains, and this, I fear, is not likely to survive the present severe winter, although on a well drained rockery and protected by glass. However, as the plant is at least six or seven years old I must not complain.—R. E. H., *North Somerset.*

AN APPEAL.

We have received the following from the Countess of Carnarvon:

SIR,—Last year a box of vegetable seeds was, by the kindness of a friend, distributed among the destitute refugees in Albania. This year a little waste plot of land was cropped with excellent English vegetables.

There are many other refugees in Albania, whose sole food is such maize as they can get. May I appeal to all those who have gardens to send packets of seeds, small or large, to the Hon. Secretary of the Albanian Fund, 28, Bruton Street, London, W.1, for transmission to Mrs. Pennington, the lady who is in charge of the refugee work in Albania. I can assure them that the seeds will be most thankfully received, and the produce will be of the greatest use to the little children. —E. CARNARVON.

PLANTS TO AVOID

AMONG the many mistakes which the novice in gardening is apt to make, that of introducing plants which prove cuckoos in the nest is one of the most annoying, if not the most serious. He—the tyro—is fascinated by a specific description in a catalogue, or something growing prettily and innocently in a friend's garden attracts his eye and he promptly buys or begs a root—the friend is usually kind enough to spare him quite a big piece—plants it in a carefully chosen spot and forgets it for some months. When at last he remembers to look for it he finds it healthy and flourishing; but its less vigorous neighbours, where are they? Simply squeezed out of existence. Tussilago (Petasites) fragrans is one of the worst of these piratical plants, but, fortunately, its evil habits are fairly well known, and it has no beauty to be a temptation. Campanula glomerata, on the other hand, which is nearly as much of a cuckoo, is rather a handsome thing, and its rich deep purple flowers are good for cutting, but in a light soil its rapacity is unbounded. In my garden a year ago it was chopped back to a piece a few inches across; now its pale green leaves cover many feet of the border; it has thrust its way into a clump of Iris sibirica; choked Sedum spectabile to death; its shoots have come up all over a patch of long-spurred aquilegias, and it is getting well into the edging of pinks. Senecio tanguticus is another piratical plant. Its tall golden spikes are very striking, whether grown in the wild garden—the safest place for it—the border, or arranged in big jars for house decoration; but its stoloniferous roots run for an immense distance, and if any tiny scraps are left in the ground when its curtailment is attempted each will grow rapidly into a lusty plant. Only a severe and prolonged frost will check its activities.

Thermopsis montana is one of those tiresome plants that will not "stay put." It is not particularly rampant in growth, but in my garden it has completely disappeared from its original place and has worked its way across the border, tried conclusions with Erigeron speciosus and some delphiniums and, passing on through them, this last summer its pretty yellow lupin-like flowers appeared among the kale in the vegetable plot in the rear. Polygonum cuspidatum, known to some people as "false bamboo," is emphatically a plant to be avoided. Its curving sprays with their feathery white flowers are undoubtedly very graceful, but it increases with incredible speed and is nearly as difficult to eradicate as the large white convolvulus (Calystegia sylvatica), which some years back was advertised in some newspapers as a nameless but wonderful "climbing plant that would grow 15 or 20 feet in a season and improve every year." This was a perfectly true description, but . . . I wonder how many of those who were tempted and fell are still trying to get it out of their gardens? This convolvulus is particularly dangerous if it gets a strangle-hold on a shrubbery.

The hawkweeds must be placed on the index, especially the common Hieracium aurantiacum, whose name in the vernacular is the extraordinary one of Grim-the-Collier, a plant, which, indeed, has nothing to recommend it save the glowing orange-red of its rather trivial flowers. Centaurea montana, although its bad habits are scarcely marked enough to call for its entire exclusion from the garden, is an irrepressible sort of plant which needs close watching, and its roots are not only rambling, but go very deep, and so are hard to extirpate.

Unfortunately, there are more than a few cuckoo plants that are particularly happy (and destructive) in the rock garden. The common Saxifraga muscoides—Dovedale moss, Eve's cushion—is useful in its proper place, but it should never be allowed to approach choice alpines, as little by little it will work its way into them and, unless it is drastically dealt with by means of a kitchen fork and patience, they will soon disappear under the moss' fat green cushions. The acænas, A. inermis and A. microphylla, can be nearly as overwhelming as the saxifrage, their dense carpets of bronze-green leaves spreading with great rapidity, A. inermis being the worse culprit of the

Digitized by Google

two. But infinitely more undesirable is Helxine Solierolii. In a garden that I know this villainous plant, originally placed behind the stone edging of a border, has crossed a paved path by working through the joins in the flags and annexed a large piece of an adjoining grass-plot, whence it cannot be removed by any means short of stripping the turf off. And as it turns black with the first sharp frost—this, alas! has no effect on the roots—it is a hideous eyesore during the greater part of the winter. When it has not got into grass and there are no valuable plants close by, helxine can be fairly effectively dealt with by means of the kitchen-fork and a kettle of boiling water; but these heroic measures are not always possible. There are, of course, many other plants of the cuckoo type; in these notes I have only dealt with those I have found most troublesome in my light and shallow soil which is very full of lime. No doubt the experiences of those whose soil is on the heavy side would differ materially from mine. R. E. HEAD.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

VEGETABLES

THE SPROUTING OF SEED POTATOES.

I AM frequently asked, as a horticultural teacher, to state whether the sprouting of seed potatoes has any value. Invariably my reply is in the affirmative, because I have sprouted my stock for many years. An earlier crop is one of the gains I perceive as a result of that process. A sprouted crop is ready for lifting fully a fortnight earlier than an unsprouted crop growing under precisely the same conditions. Tubers affected by sprain are isolated by sprouting. This mysterious disorder paralyses the functions of growth. The grower may be certain that tubers which develop very weak sprouts or refuse to sprout at all are affected by sprain. He may be equally certain that it would be a mistake to plant them. The sprouting of seed potatoes also helps to identify rogues in the stock. It is rare for two varieties to bear sprouts which have a like appearance in every respect. A key to sprout identification is given by the Scottish Board of Agriculture in a little book which they issue at the nominal price of sixpence. The isolation of rogues may not be very material if both varieties are good croppers and immune from wart disease; but it is a matter of great moment if a susceptible rogue is inserted in infected soil. The sprouting of the stock, by stimulating an even growth, results in a heavier yield. Some experiments which I conducted two years ago gave a yield of one ton per acre more in favour of sprouted as against unsprouted seed. The most satisfactory sprouts are formed when the tubers are set in shallow boxes with the rose end upwards, in a light situation and in a temperature which does not descend below 35° and does not ascend above 45° on the Fahrenheit scale.—GEO. H. COPLEY.

A TRENCH GARDEN.

FOR growing early crops of lettuces and other salad plants there are few devices to equal the trench garden. This is formed by digging a trench in the ground which may be of almost any length. The trench should be about 18ins. in depth and 2ft. wide, and it is better to have it running north and south. The soil at the bottom should be well dug and, if necessary, enriched.

Protection for the trench garden is secured in this way. Over the top are rested laths of wood, and on to these pieces of glass are placed. Any odd bits of glass will serve, and if these are uneven in size and shape it does not matter at all. The writer used a number of cleared-off photograph negatives for this purpose with good results.

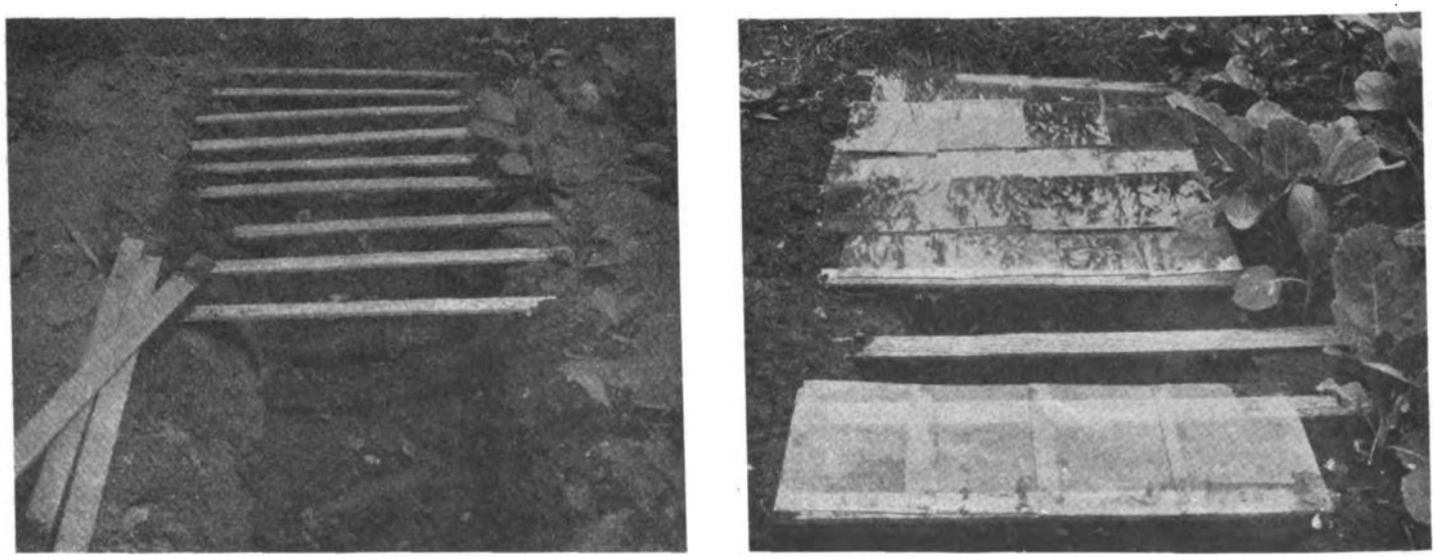
Naturally, if wished, it is easy to turn the trench garden into a hot-bed by packing suitable material into the bottom. Here the trench should be opened up to a somewhat greater depth. Being sunk in the ground the trench garden retains its heat to a remarkable degree.—S. LEONARD BASTIN.

CELERIAC.

LAST year our crop of this vegetable was the best we have ever had. Previous to last spring, we had always sown it in gentle heat and pricked it off outside after hardening. Last year, for a change, we pricked it off into large boxes under glass, getting thus a stronger plant to put out, and the result has justified the method. There are a number of ways of cooking and serving this agreeable vegetable, and the reason it is not far more grown is hard to seek. I wonder if any of your more botanically inclined readers can throw any light on its origin. I do not think it possible that the stock can have been derived from a plant of pure celery that merely sported into a form with an enlarged root, because there is a very pronounced flavour of parsnip to be discerned. In conversation with one of our leading vegetable growers and exhibitors recently, I found he leaned to the opinion that celeriac was a hybrid between celery and parsnip. I wonder if these two subjects are sufficiently nearly allied to have made this theory possible?—EAST SUSSEX.

POTATO TUBERS: THEIR EARLY PLANTING.

THE time of potato planting has come once more; first in pots, boxes and frames, then in warm outside borders, followed by the main planting in the open quarters. But the wise cultivator will not delay examination of the tubers. The latter should have their full strength preserved, and to this end the cultivator should see that every tuber is exposed to as much light as possible, also cool air, provided there is not any frost. Full ventilation of the seed tuber stores and the maximum amount of light during fine weather should be the rule. But these conditions would not avail much unless the tubers were fully exposed in thin layers, not in thick ones or under straw coverings. An ideal condition would be one in which the tubers of the early kidney sorts were placed in single layers in shallow boxes, eyes upwards; and the later varieties in double layers on floors or shelves in cool, light sheds. Thus treated, every tuber would retain its full strength, as only surplus sprouts would require to be rubbed off at an early stage. Those retained would be short and sturdy and not easily broken off by the



A TRENCH GARDEN FOR EARLY SALADS.
Laths of wood placed across the trench. With sheets of glass in position.

Digitized by Google

covering soil. Ideal potato soil is a light one, moderately rich. In pots, boxes and frames, such composts may be procured on a small scale very easily. In the large open quarters the thorough breaking up of the soil while in a suitable condition will help very much. Clean leaf-soil and old, well crumbled manure will prove very beneficial to the early crops especially.—GEO. GARNER.

FLOWERS

THE BLUE PERENNIAL FLAX.

NO one will regret finding a place in the garden for the blue perennial flax (Linum perenne). This plant increases very rapidly in size from the seedling stage and soon the grower has big clumps which are covered with large sky blue flowers round about midsummer. The seed of L. perenne should be sown in a nursery bed in the open in March. Only just cover the seeds with soil and as soon as the little plants come up, leave them where they are until large enough to remove to the permanent quarters. Of course, if the seedlings are jostling one another, thinning out is advisable. The blue perennial flax grows to the height of about a foot or 14ins. and it seems to do well in almost any aspect, save perhaps one facing due north. Of course, the plant is really a lover of sunshine and it is always at its best when on a south border. Fine displays of blossom are, however, secured in other positions and these will be somewhat later, so that a succession of bloom is secured. This linum is not particular about soil providing the drainage is good; in fact, it is often extremely floriferous in places where the ground is dry and of poor quality. There is a white variety, L. perenne album, but most people will prefer the lovely blue flowers of the type. The stems of this plant are very slender and should be given some support as rain or wind will otherwise do a lot of damage. A good plan is to support fine mesh wire netting over the clumps as the individual staking of so many stems is a tedious business. The blue perennial flax makes a fine edging for a wide border and it may also be effectively used in the rock garden.—S. LEONARD BASTIN.

WALLFLOWERS AND HARD WEATHER.

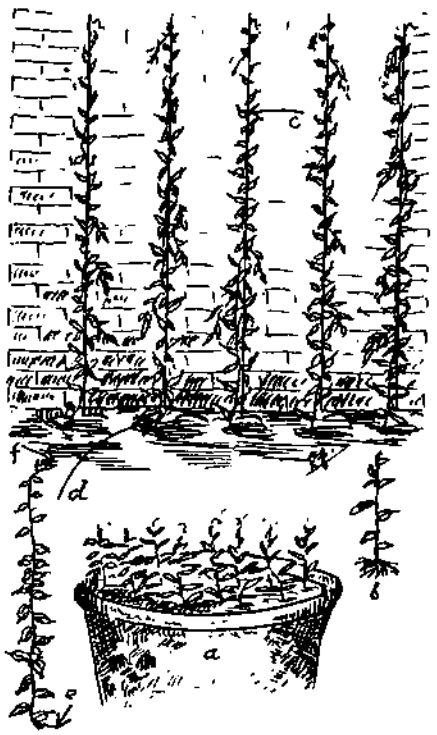
THE very severe weather experienced this winter has taken its toll, in many places, of wallflowers that were got into their permanent quarters in October, and, in some instances, later. From between four and five hundred plants shifted in October, I do not appear to have more than a dozen losses, and these were among the largest plants. I attribute my having had so few failures to three things, *viz.*, sowing seed at the end of May, pricking seedlings out early in comparatively poor ground, and in lifting each plant with a ball of soil so as to disturb the roots as little as possible. It was a laborious task at the time, but the trouble has been justified, and has proved conclusively that soil entirely free from manure—poor, in fact—meets the needs of wallflowers and produces those stiff, bushy little specimens that in time of frost and snow quickly recover as soon as weather conditions improve with a minimum of losses.

When one sees plants got out of nursery beds late in November with little or no soil and most of the roots exposed, one is not surprised to learn that such plants, not having time to become established, are the first to go under in the first snap of frost. It would be surprising were it otherwise, as, after all, there is such a thing as a limit to endurance of plants subjected to treatment as that described on the threshold of winter.—W. F.

GREENHOUSE

SMILAX.

I AM sure many readers of THE GARDEN have noticed the kind of foliage that surrounds flowers while the latter are growing, and the suitability of such foliage. It is not always possible to use the foliage with the flowers in a cut state, so we are obliged to substitute some other kind. Fern fronds are mostly employed, but are not always obtainable, nor is it desirable to cut them too



severely, especially in cases where the plants are appreciated for their individual beauty. So more cultivators should try to grow asparagus ferns and smilax—known also as Medeola asparagoides. There is the original variety and the improved sorts, the latter being considered improved owing to the smaller leaves and more delicate stems. The original variety is stronger growing and fills more space in a short time; the plants are charming, trained to wires, for furnishing the back walls of greenhouses and conservatories, and to strings if required for cutting purposes. The small-leaved varieties should be treated in a similar way where lower walls are concerned. When the string is cut at both ends the smilax trail can be readily withdrawn. Use as a compost throughout sandy loam, a small quantity of peat or leaf-soil. Sow the seeds in pots or pans in February in a warm greenhouse. At *a*, the young plants are shown ready for transplanting to their permanent positions; *b*, a plant as lifted from the seed pot; *c*, the plants clinging to strings; *d*, smilax planted out, but they may be grown in large pots. At *e* and *f*, a plant is shown cut and freed from the string. Occasionally, old plants will flower freely, and they are sweetly scented.—G. G.

PINCHING SWEET PEAS.

SWEET PEA WARRIOR.

NOW that the sowing season for sweet peas is with us, it might be interesting to throw a sidelight on pinching. A plant—variety Warrior—was overlooked at the date (December 15th, 1924) when the other plants in the same large pot were pinched. In January, however, the plant was taken out of the big pot and pinched. It was then 7½ins. high and had twelve fully expanded leaflets. In removing the plant from the soil the main tap root was severed, but several side roots and rootlets were left. The plant was set in a mixture of sand and loam in a 3in. pot. After being potted up the plant was kept in the early vinery for about a fortnight, and so placed that sunshine would not reach it for that period, as we wanted the plant to grow well, hence the care to get it re-established after the somewhat drastic treatment in extracting it from the large pot. A month later the plant showed an additional young growth of 3ins. and twelve or more fresh roots, measuring from 1½ins. to 2ins. long. This young shoot had arisen from quite near the base of the first stem at a quarter of an inch above the soil level. This young strong stem was pinched and the plant transferred to a 5in. pot. To the soil mixture was added some old lime and firm potting was avoided. The plant was then returned to the late vinery, and here, except for watering, it was left alone for another month.

The progress, when examination was made in March last, was interesting and worth recording. There were plenty of fine white, healthy roots which had ramified through the soil at the inside basal end of the pot. The shoot which was 3ins. high and pinched a month ago had now four side growths, and, strange to say, the lowest growth was largest, being 1½ins., the next growth was about 1in., while the two top growths measured each less than 1in. In March the plant was accommodated in an 8in. pot, and to indicate what a great stride had been made one strong stem had made a growth of between 11ins. and 12ins. for one month between March 18th and April 18th. The tall shoot showed green flower-buds on April 22nd and the first flower showed colour on May 8th.

This, of course, is an example of pinching, and in a sense one might say it had been overdone, yet it did not deter the plant from producing flowers as early as those plants which had never been pinched.—DAVID ARMSTRONG.

THE ROSE HOUSE.

AT the present time the plants present a somewhat ragged appearance in many houses where they are grown under glass. But the rose enthusiast knows at once when he examines his favourites whether they are in a promising condition or not. In imagination he sees the lovely blossoms borne on the strong stems. To procure these strong stems he must hard prune some varieties and severely thin out the branches of others. It is quite time now to do the work of pruning. Where the plants are grown in open borders under glass, or in large pots there, a fine succession of blooms may be obtained by judicious pruning. The shoot bearing the flower is cut off rather low down, but two or three buds are left. Almost immediately these buds begin to grow, and in five or six weeks time flowers on them are available for cutting, and so we go on. But all this means working the plants at very high pressure, as it were, and we should feed them liberally each time new shoots are growing. To delay outside-grown plants the young shoots are stopped when they are about 4ins. long, then a harvest of blossom is available a month or so later than is usual from the spring pruning. Inside plants are too precious to be treated in this way. If young roses are to be planted inside now, the structure should be kept well ventilated. When the established plants have been pruned, cleaned and in some cases tied up, the surface soil should be carefully removed and replaced with fresh fibrous loam and bonemeal or other approved stimulant; also thoroughly water the soil.—HANTS.

BOOK REVIEW

ORNAMENTAL TREES FOR AMATEURS.

MR. BEAN is to be congratulated in the production of this little book, "Ornamental Trees for Amateurs" (*Country Life*, price 5s.), which is intended as a companion to his "Shrubs for Amateurs," published in 1924. It is one of the series issuing from the offices of *Country Life* on special gardening subjects, and to the many who are now interested in growing ornamental trees, this book will be found of especial value. The book is written in the usual concise and readily understandable language of the author and is the concentrated essence of a life of practical experience among trees. The information is given in a form that may be readily utilised by those for whom it is specially intended. At the present time, when so many smaller gardens are in the making, it will prove a boon to the planter, both in its cultural details as well as in the assistance he will desire in making a good selection for the particular site which he intends to plant and prevent him falling into errors that can only be rectified at a later date, with considerable trouble and expense. The chapter on cultivation gives a clear idea of the best methods to adopt in preparing the ground for the reception of trees, so as to secure the best results, whether the trees are destined for borders, or specimens on the open lawns. A chapter on propagation comprehensively describes the raising of young plants from seed, cuttings, grafts and layers, and a careful study of the methods recommended will enable the amateur to attain successful results by following the instructions given. Transplanting and pruning are also dealt with fully both for deciduous and evergreen plants and the dangers of carrying out the operations at the wrong period of the year are pointed out. In pruning, general rules are laid down, details of which branches should be removed and those to be left are described in order to attain the best results in the ultimate tree.

To the "Care of Old Trees," several pages are devoted and the advice given will be appreciated by those having such examples under their charge and whose duty it may be to take the best steps for their preservation.

Lists of trees suitable for large and small gardens have been chosen from both evergreen and deciduous genera. There are also good selections of trees which are attractive either for their flowering, fruiting, coloured foliage or for their pendulous habit.

By turning to the descriptions of genera and species which occupy about eighty pages, a good idea will be gained as to the likelihood of any plants mentioned in any of these lists being suitable for the purpose of the intending planter. The genera are arranged in alphabetical order with a good index, and the common names given where possible, a distinct advantage to those unacquainted with the botanical one. Fifteen full-page illustrations are interspersed through the book, showing excellent examples of some of the trees described.

PUBLICATIONS RECEIVED.

"The Families of Flowering Plants.—1. The Dicotyledons," by J. Hutchison, F.L.S., published by Messrs. MacMillan and Co., Limited, St. Martin's Street, London, price 20s. net.

Hand List of Conifers Grown in the Royal Botanic Gardens, Kew. Third edition, price 1s. 6d. net, obtainable from the Royal Botanic Gardens, Kew.—This little handbook enumerates 288 species and 398 varieties of coniferous plants and in addition sets forth a list of cycads in cultivation at Kew. Space is also devoted to the economic properties of the gymnosperms. The lists, in the first section, are arranged alphabetically in the families and not botanically as was the case in former editions, while in the second section, the botanical arrangement has been retained. The establishment of a national arboretum at Bidgebury, where the cultivation of all conifers will be undertaken in future, is also referred to. It is a little handbook which certainly all professional gardeners and not a few amateurs should possess.

The British Journal Photographic Almanac, 1926 edition, 880 pages. Henry Greenwood and Co. Limited, Wellington Street, W.C.2, price 2s. net. All photographers will welcome the publication of the sixty-first annual issue of this almanac, the encyclopædia of photographic information. All that an amateur and professional worker could wish for is given in its pages, set forth clearly and concisely. Instructions are to be found in every phase of photography, while much useful information is given in all the new and latest appliances which have made their appearance since the last issue. A mine of information to photographers.

"Soils and Fertilisers," by A. J. Macself. Messrs. Thornton Butterworth, Bedford Street, Strand, price 6s. net. Another member of the "Home Garden Books."

CATALOGUES RECEIVED.

Messrs. Wm. Jones and Co., Waterford.—List of Seeds for 1926.

Messrs. Isaac Poad and Sons, Limited, Seed Potato Grower, York. A useful list of seed potatoes for 1926 which should be in the hands of all gardeners.

Messrs. Fidler and Sons, Royal Seed Stores, Reading.—A catalogue of vegetable and flower seeds, Scotch potatoes, etc.

Messrs. Ransomes, Sims and Jefferies, Ipswich.—An illustrated list of their famous lawn mowers and rollers. Motor mowers as well as hand mowers of all types and sizes are included.

Messrs. Carter Page, 52, London Wall, E.C.2.—A catalogue of vegetable and flower seeds, perennials and biennials for spring planting, and a good selection of violas. A useful table, giving directions for vegetable culture, is included.

Messrs. E. P. Dixon and Sons, Paragon Square, Hull.—A well printed catalogue of flower and vegetable seeds, ornamental grasses, bulbs for spring planting, and various garden requisites. Many helpful hints are given.

Mr. A. G. Vinten, Oldland Nursery, Balcombe, Sussex.—A catalogue of choice chrysanthemums. Some of the finest early-flowering single varieties are listed.

Messrs. Robert Sydenham, Limited, Tenby Street, Birmingham.—A concise list of vegetable and flower seeds. Many sweet pea novelties and herbaceous perennials which can be raised from seed are included.

Messrs. John Waterer, Sons and Crisp, Twyford, Berks.—Seeds for the vegetable and flower garden. Also bulbs and roots, such as tuberous-rooted begonias, spiræas and ranunculus, are listed.

Messrs. Harrison and Sons, St. James' Street, Leicester.—A good seed list of standard varieties of flowers and vegetables.

Messrs. R. H. Bath, Limited, Wisbech.—A select list of garden seeds and plants. Some interesting flower and vegetable novelties for 1926 are included.

Mr. H. Eckford, Wem, Shropshire.—A catalogue of sweet pea varieties both new and old has been sent in by this well known sweet pea specialist. Flower and vegetable seeds of all kinds are also listed.

Messrs. Dobbie and Co., Edinburgh.—Plants for spring planting—an interesting catalogue. It contains many fine varieties of asters, dahlias, chrysanthemums, delphiniums, and a most useful list of bedding plants.

Messrs. W. Cutbush and Son, Barnet, Herts.—A catalogue of garden seeds, gladioli, horticultural sundries, etc.

Messrs. Joseph Fison and Co., Ipswich.—An interesting booklet on fertilisers for the garden and greenhouse comes from this long-established firm of fertiliser manufacturers. Notes on the value and uses of various chemical fertilisers, and the rate at which they should be applied, are given. A very useful table, giving directions for sowing vegetable seed and the rotation of crops, is included. All gardeners should make a point of applying for this publication.

Messrs. E. Webb and Sons, Limited, Wordsley, Stourbridge, Worcs.—Vegetable and flower seeds, lawn grass seed, potatoes, bulbs, garden fertilisers, turf preparations, etc. Illustrations of many of the fine strains of flowers and vegetables stocked by this firm are included. There are careful detailed descriptions of each variety.

Messrs. Toogood and Sons, Limited, Southampton.—A flower and vegetable seed catalogue for 1926. A useful and concise order form is supplied, and the many illustrations give some idea of the excellent strains which have been obtained by rigorous selection. All seeds sent out by these seed merchants are guaranteed.

Messrs. Thompson and Morgan, Ipswich.—A well compiled descriptive list of choice flower and vegetable seeds, perennials, biennials and annuals, is given. This catalogue will interest the alpine enthusiast particularly. Many of the finest primulas, saxifrages, androsaces, campanulas, etc., in cultivation are included.

Messrs. Alexander and Brown, Perth.—This firm is to be congratulated on their excellent publication, "My Garden Book." Throughout the 100 pages of this book are numerous half-tone illustrations and colour plates. The cultural details and notes on garden pests should be of great service to the amateur, who would be well advised to study this publication before making out his seed lists.

FOREIGN.

Messrs. Ant. Roozen and Son, Overveen, near Haarlem, Holland.—Bulbs, herbaceous plants, roses, etc., for spring planting.

Messrs. Vilmorin-Andrieux, 4, Quai de Mégisserie, Paris.—A catalogue of flower and vegetable seeds. Many uncommon vegetables and herbs are stocked by this firm, and a number of recent introductions which they are offering for the first time are described.

Messrs. Henry A. Dreer, 1306, Spring Garden Street, Philadelphia, Pa.—Comprehensive Garden Handbook for 1926, containing vegetable and flower seeds. This catalogue is profusely illustrated by means of numerous half-tones and one or two coloured reproductions.

DIDISCUS CŒRULEUS.

It has been brought to our notice that seeds of Didiscus cæruleus, which was mentioned by Miss Victoria Slade in a note on "Two Blue Annuals," are listed by several well known seed firms both in Scotland and England. Our contributor's statement that the annual was practically unknown in Britain is, therefore, misleading.

GOLD MEDAL OFFERED FOR ALPINES.

THE Council of the Royal Horticultural Society has decided to offer a gold Veitch Memorial medal for the best exhibit of alpines in pots and pans staged by an amateur at the Society's fortnightly show on March 23rd, 1926.

CARTERS NEW TOMATO "EPICURE"

AND 24 OTHER NOVELTIES ARE LISTED IN OUR CATALOGUE FOR — — 1926 — —

CARTERS NEW TOMATO

CARTERS EPICURE TOMATO.—A seedling from *Sunrise*, crossed with a selection from *Duke of York*, the fruit is intermediate in type between these two varieties, being larger and a little less spherical than *Sunrise* but not possessing the flatness of *Duke of York*.

Both in our indoor and outdoor trials, this new tomato has proved itself of exceptional merit, being particularly thick fleshed, and containing very few seeds.

The trusses average 8-10 fruit of very even size. We know of no variety which produces such a high percentage of even-sized fruits, it being quite exceptional to find any either larger or smaller than the normal type. Per pkt., 2/6 and 3/6

BEGONIAS

BEGONIAS, tuberous-rooted varieties, both single and double, are easily raised from seed, which may be sown at any time during January or February. If well grown a large proportion of the plants will prove useful for the greenhouse during late summer and autumn, thus forming a good succession to the earlier-flowering batches grown from dry tubers.

The seed pans should be well drained and filled with a light, sandy compost, which should be watered from a fine-rosed can some hours before the seed is sown. The fine, dust-like seed should be distributed evenly over the surface, and should not be covered. Place a piece of glass over the seed pan and keep shaded until germination takes place, standing the seed pan in a house with a temperature of 60°; if a little bottom

heat can be given, germination will be hastened.

When germination takes place, the seed pan should be placed up near the light, keeping the covering glass on for a few days, but admitting a little air and keeping it shaded during bright sunshine. The young seedlings should be pricked off into pans of light, rich soil; it is not necessary at this stage to prick them off singly, as they may be transferred in small tufts to the fresh soil; the next time they are moved it will be much easier to separate them out singly.

Success depends very largely on their being grown quickly without any check, thus frequent shifts are necessary into shallow boxes of light, rich compost. If well grown they should, from the beginning to the middle of May, be ready to plant out in beds of rich soil in cold frames. When they have attained some size, a few of the strongest plants may

be lifted and potted up for use in the greenhouse, while the bulk of them should be planted in the reserve garden, where they will make good tubers for next year.

Begonia sempervirens, of which there are many fine varieties, may be sown from now onwards until March; they are largely used for summer bedding, but in the colder parts of the country they are equally useful for conservatory and greenhouse decoration. They succeed under the treatment indicated for the tuberous-rooted varieties.

EVERLASTING FLOWERS WORTH GROWING.

IT has to be said concerning flowers most of which can be grown out of doors and have a value for the home because of their lasting properties, that the average gardener takes but a negative interest in them, if, indeed, he is not almost indifferent to their beauty and use in the home. Most of us, if we have not despatched our seed orders, are, at any rate, pondering on our selections, and I would urge upon those who have never seriously taken "everlasting" flowers into consideration to do so in the coming season, and give them a place in the garden. Annuals, biennials and hardy perennials all furnish something that in their time of blooming may be cut and preserved for use when the garden is bereft of flowers. In annuals alone we have some that are exceptionally attractive, like rhodanthes, acrocliniums and helichrysums. The first named is a favourite with many for pot culture, the rosy pink and silvery, dainty blossoms being most acceptable for table and window adornment, but rhodanthes, along with the other two mentioned, can be successfully dealt with if seed is sown out of doors on a warm border in May. The glistening silvery pods of that old-time biennial lunaria, known by its familiar name as Honesty, should not be left out of count. It should be noted, too, that the annual forms of statice if sown and reared under glass until it is time to plant them out in May will provide a wealth of colour. Clumps of perennial statice, like latifolia with panicles, of bluish purple blossoms, together with eryngiums (sea hollies) and echinops (globe thistles), if planted in good time in March, will provide flowers the first season, and gypsophila will do so the second season after planting. Physalises are resplendent in the rich colouring of their pods, and are very popular. If planted at the same time as the other perennials, they seldom disappoint. —W. F.

CELERY WITHOUT TRENCHES.

NOT being quite satisfied with my celery plants on many former occasions, I decided one year to grow the plants on the surface of the soil instead of in trenches, and my method was as follows: Early in June lines were marked off for the plants, then grooves were made only a few inches deep and 1ft. wide. Next, the soil in these grooves was turned over and leaf-mould incorporated as the digging proceeded, and on this prepared ground the plants were set out in single lines. The plants soon grew apace, and to assist them further we dug shallow trenches the width of the spade and the whole length of each line—on one side only—a few inches away from the plants. Into these trenches we placed a good mulch of farmyard manure, and over this the soil which we took out. The time of applying this mulch (June 25th), was a fortnight after the plants were first set out. Sandringham White was the name of the variety which received this treatment. When the stems were sufficiently grown the soil was banked up on either side of each row, so that each plant was surrounded with soil for blanching purposes. I recommend this method to all who have to grow celery on heavy soils.—D. A.

Launching an offer of Seeds for trial.

Free and Post Free.

We launch this offer with much the same feeling in which we should approach thin ice—gingerly—because the offer might be thought to somewhere hide the cloven hoof.

But as we are neither asking for money nor making any conditions whatever in offering to send seeds free to anyone who cares to ask for them, it is difficult to see where the hoof could be hidden.

In the hope of getting into touch with a larger number of gardeners than we now have the pleasure of serving, we are sending to all applicants, free and post free, one packet each of three remarkably good vegetable seeds:

BEETROOT—BAKERS' SELECTED GLOBE. A beautifully formed round beet with a conspicuously thin tap root. . . . .

PARSNIP—GOLIATH. The biggest and best Parsnip that has ever come our way. . .

ONION—MONARCH. The largest growing, best flavoured Onion among those that really keep.

All we ask is that only responsible people will send for the seeds and that they will do their best with them when they get them, because it is only on results that we can hope for the distribution to benefit us.

Where results are good we hope that the grower will be encouraged to learn for himself what Bakers' other seeds are like and so bring grist to our mill.

For our part we can assure all such ladies and gentlemen in advance that the behaviour of the three varieties of seeds we are sending may be taken as a trustworthy guide to the growth and production of all the seed we sell.

Bakers

SEED & FLOWER FARM, CODSALL. *Nr. Wolverhampton.*

To anyone who is diffident about sending for the free seeds we shall be glad to send a copy of our complete Seed Catalogue. In many ways it is an unusual list—more informative than most—certainly more comprehensive and with something about it that might be called the "human touch," as distinct from the cut and dried, soulless sort of production most of us are used to.

A SHRUB GARDEN IN CORNWALL

THERE are many amateur gardeners who have commenced raising a collection of flowering shrubs, but who, through lack of success, are inclined to throw up this most fascinating hobby for something easier and with quicker results. For the benefit of these, and as a stimulus to continue their efforts, I would like to introduce them to a "one man" collection of shrubs and briefly describe some of its contents.

Mr. Percy Waterer was once well known in sweet pea, chrysanthemum and rose circles, and largely exhibited in all three subjects. Seventeen years ago he retired from the City and, settling in Cornwall, took up the hobby of raising hardy flowering shrubs. At that time his knowledge of such shrubs was practically nil.

Situated about two miles inland on the south coast and near Penzance, his garden, which totals about 2 acres, is lying on a steeply sloping hill facing north-north-west; on his arrival there it was croft land covered with gorse and heather, yet single-handed he has transformed it into a perfect Elysium for shrub lovers. Never have other hands taken part in the transformation—not even for the heaviest digging or excavation, and the garden is now a worthy monument to continued hard work, patience and perseverance. A brief description of the place will show what can be done single-handed.

Entering by the west gate, we find a broad avenue with the main garden running steeply up the slope on the left, on the right being a small shrubbery containing his first efforts at shrub raising.

In each of two corners of the latter is a huge Royal fern raised from seed, and near by is a well grown Eucryphia cordifolia carrying a fair amount of bloom. Strolling along the avenue, we pass E. pinnatifolia, Desfontainea spinosa, Leptospermum Nicholsii, L. Chapmanii, L. Boscaweni and L. lævigatum, the glorious Embothrium coccineum in close company with a fine Tricuspidaria lanceolata. On the eastern side one is immediately struck with a very fine specimen of Olearia Solandri, its new growths glowing like gold in the sun; and from here may be seen O. semidentata, Clianthus puniceus (grown as a bush), Magnolia stellata, a 24ft. Drimys Winteri, Myrtus bullata and others too numerous to mention. Passing a small rose garden, we proceed towards the house, noticing on our left a large clump of Olearia insignis, a massive Acacia dealbata, in the shade of which is a 10ft. Plagianthus Lyallii, Pittosporum Ralphii, Leucopogon Richii and L. fasiculata. On the right are Acacia Baileyana, Diosma gracilis, Rubus australis, Olearia virgata, Bauera rubiæfolia, Corokia buddleioides and others, backed by various buddleias, veronicas, fuchsias, Eupatorium Weinmannianum and Polygala Dalmaisyana.

Turning sharp to the left, we observe a bank of Mitraria coccinea, the coral red blooms showing up well against the dark green background; while opposite is a well furnished Leptospermum flavescens. Another turn brings us face to face with a large bank of heaths, composed principally of Erica arborea, E. codonodes and the true E. australis. Looking right, we get a glimpse of the house with Prostanthera rotundifolia, Erica melanthera and Passiflora cœrulea climbing its walls; while the border leading thereto contains Clethra arborea, Myrtus communis, Rhododendron Pink Pearl, Euphorbia mellifera and the daintiest of dainty shrubs, Diosma uniflora and Pentapterygium rugosum (How I envy these!)

Mounting still higher, we pass a profusion of berberis of many varieties, the exquisite colourings of their berries brightening the dull days; Cytisus præcox, Escallonia Mayii, Dianella intermedia (its berries now a glorious blue), and at the very top of the hill we espy wonderful trees of Acacia juniperinus and retinoides. From this vantage point we see numbers of Cordyline australis, C. Banksii, C. indivisa and eucalyptus rearing their heads above the trees and shrubs, and can just see Clematis Jackmannii intermingled with Solanum jasminoides clothing one side of the house with bloom.

The first feeling experienced after visiting this place and viewing the enormous labour involved in its creation from practically virgin croft, is one of amazement that one man could perform the task unaided; and the second feeling, the great patience and perseverance required to carry it through. There are many finer gardens, many finer and rarer collections of shrubs, but never have I seen a garden where one man has produced finer results. Do not think that even in this delectable spot no difficulties are to be overcome. Hurricanes from the Channel, a constantly damp atmosphere, sudden and severe frosts in early spring (twenty degrees of frost have been registered here), are but a few of the trials; and, as a tonic to those shrub enthusiasts who have suffered disappointments and are despairing of success, I would recommend either a visit to this garden or the adoption of the owner's two mottoes: "Patience, perseverence and hard work," and "Love your plants, watch your plants. They will tell you what they want when they want it." Further, to remember that practically everything contained in the garden described has been raised from either seed or cuttings.—P. E. CHAPPELL, *Cornwall.*

SCOTCH SEED POTATOES

CLASS 1.

Selected Stocks of the Leading Varieties.

Send for List.

ISAAC POAD & SONS, Ltd.,

Seed Potato Growers - - - YORK.

Glass breaks!

WHY USE IT?

'WINDOLITE'

The practical Glass Substitute for all GARDEN USES.

Light. Flexible. Unbreakable.

Easy to cut and fix. It keeps out cold and wet, but lets in all the light—even the Ultra Violet Rays which are stopped by glass.

Send 4/6 for post free sample, 3 ft. by 2 ft.

To Amateur Gardeners.

Years ago I put to myself the question, "Can I do anything to enable the man with a small garden to grow quality seeds and so obtain the best possible results from his labour?"

It was this desire which originated my now well known policy of supplying quality seeds in popular quantities, and it is this desire alone which remains to-day uppermost in my mind.

Samuel Ryder

Plan Your Garden

ALMOST within the next week or two, you will be out again in the garden, and, no matter how "tidy" you may have left it in the late autumn, there will still be more than enough to occupy every minute you can spare in preparation for your Spring sowing.

NOW

It may seem ridiculous to suggest that your first gardening "job" for 1926 should be done now, in your armchair, before the evenings are even light enough for you to see your own tool shed door.

And yet every practical gardener knows that the suggestion is a sound one. Plan your garden NOW. Make up your mind what you are going to grow and where you are going to grow it. Flowers here and vegetables there, and so on. It will save a lot of trouble and thought later on.

To help you, the new (1926) Ryder Catalogue-Guide is ready for immediate distribution. Just sit down and fill in the coupon below to-day, not to-morrow, and a copy will be sent you by return of post.

Quality Seeds in 2d. Packets

(FLOWER AND VEGETABLE)

The great advantage in buying Ryders Flower and Vegetable Seeds in 2d. Packets is that you obtain seeds from quality strains in any quantity you require, from twopennyworth upwards, according to the capacity of your garden.

£1000 COMPETITION.

This Competition is open to anyone who purchases goods to the value of 2s. 6d. or over. A very fine collection of flower seeds, valued at 3s. is sold for 2s. 6d., and it contains the eighteen varieties from which you are asked to choose the twelve most popular. We feel sure that if you grow these beautiful annuals you will have no difficulty in voting for their order of merit.

1926 GARDEN CATALOGUE FREE.

The "Academy Picture" Edition of the 1926 RYDER Book, containing a special reproduction in colours of Miss Winifred Walker's much discussed triumph at the 1925 Royal Academy Exhibition, full particulars of the £1,000 Competition and 104 pages of general catalogue information and gardening notes, will be sent free on receipt of the coupon below.

NOVELTIES IN THE GARDEN

THIS issue of THE GARDEN is mostly devoted to novelties. Although many gardeners prefer to grow plants of which they know the worth and of which they have had long experience, yet I think that everyone has sufficient curiosity to be willing to try out a novelty, whether it be an annual or a shrub or a vegetable. Apart from the fact that many novelties become famous plants in after years, it is necessary, as I pointed out in an article last year, in the case of annuals and vegetables, for raisers to bring out novelties from time to time, in order to keep up the general standard that is becoming higher every year. Sometimes a novelty is still-born owing to weak constitution, similarity to some other plant already in existence, or because the raiser has been over-optimistic about its excellence; but on the whole the raisers set themselves a very high standard, and buyers of a novelty may rest assured that the plant or seed has been thoroughly tested and compared with existing varieties.

It is true that many a famous garden relies for its effect on plants that have been known and valued for many years; still, there is a great satisfaction in knowing that you have something which your neighbour admires and envies and that, on the name being asked, you can say with a touch of pride that it is So-and-so which was only introduced on the market a month or two back.

Even with the general search for something better that is constantly in evidence, it is amazing how many plants, some of them known for long years in cultivation, have missed their turn of popularity. Often this is inexplicable, for their proud owners have sung their praises for long years. For some reason or other, worthy plants fall flat, perhaps because they have not received sufficient publicity. Plants that were popular a generation ago fall into disuse and even disappear from cultivation, only to be feverishly sought for if they suddenly appear in the limelight again. There are many instances of this; some of the old-fashioned auriculas, Cunningham's Sulphur rhododendron, old varieties of fuchsias, the old York and Lancaster rose, and so on. Sometimes it is due to deterioration of the stock, but it is due more often to change of fashion. This change of fashion is sometimes inexplicable, for a change in environment or method occasionally carries plants with it (*i.e.*, many of the old-fashioned bedding plants that are now used elsewhere), but sometimes the plants are left behind, which is often the flower-lovers' loss. Over and over again in turning over old gardening books, one's attention is drawn to some obviously fine plant that has now disappeared. A good example is the Cape heath, that used to be cultivated extensively at the beginning of the last century. It is rumoured that we have lost the knack of their cultivation, but I cannot believe that with all our modern methods and newly found knowledge, we are unable to grow them successfully. I hope some day to see them re-introduced as novelties and that on this occasion they may keep their popularity.

I certainly believe that gardeners of all classes and conditions are keenly interested in obtaining what is best in the plant world for their gardens, and so THE GARDEN proposes each week to publish a note and an illustration of a plant that should be seen in every garden, whether it is new, and so has suffered from lack of publicity, or old and fallen into a premature oblivion. There will be only two provisos, one that the plant must be worthy of everybody's attention, and secondly, that stocks of it are obtainable, or, alternatively, that it can be quickly raised and brought into general cultivation. We should welcome suggestions or examples from readers, but notes must be accompanied by a good photograph and should not be more than five hundred words in length.

I am sure that this will become a popular feature, for plant publicity, that was practically non-existent before the middle of the last century, has made great strides since that time. Gardeners, whether amateur or professional, are, I hope, becoming more and more inclined to trust in the judgment of others. Some are lucky and see sufficient gardens, other than their own, to be able to pick up for themselves information about plants new and old; but many who can only garden in their spare time have sufficient to do in keeping their own gardens in condition and so have to rely on second-hand information. It is with these that "Plants that should be more grown" should be especially popular. E. H. M. C.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

THE BLUE POPPIES, by F. Kingdon Ward.
THE WITCH HAZELS.
SOME EARLY SPRING FLOWERS.
ANNUALS FOR CUTTING.

PLEASE REMEMBER TO TELL OTHERS ABOUT YOUR PLANTS THROUGH THE COLUMNS OF "THE GARDEN."

TREES AND SHRUBS WORTH GROWING

ÆSCULUS INDICA.

ALTHOUGH this is a novelty number, it is impossible to advise people on what to plant in the way of woody novelties, for two very good reasons: that real novelties have not been sufficiently tested to have proved their worth for general planting, and that they are usually not procurable in quantity. The latter reason is obvious, but the first may, perhaps, require some qualifying, for the reputation of some plants precedes their introduction to cultivation in an extraordinary fashion. I shall give one instance, that of Osmanthus Forrestii. For some reason or another this has taken the fancy of all who have heard of it. So far it is in the seedling stage in this country and the seedlings are undoubtedly growing well, but its reputation rests on Forrest's description of it in its native home and on the dried specimens which certainly show it to be a fine plant, with foliage somewhat similar to Osmanthus aquifolium. On the other hand it may not come up to our expectations as a garden plant.

There are many trees and shrubs, some of them introduced years ago, that may be called novelties as far as their general use is concerned and it is with a selection of them that I propose to deal. All the plants mentioned are in commerce.

Acer nikoense is a Japanese maple that, considering its early introduction, should be far better known, for it is one of the very best of all autumn coloured shrubs—or rather small trees. The leaves are typical and are composed of three leaflets on a short, hairy stalk. Perhaps one of the reasons for its lack of popularity is its slowness of growth, but this makes it valuable for small gardens. It certainly does not develop fast, for I have found that it rarely grows more than 3ins. a year. On the other hand, it shows signs of making a shapely pyramid and I am cultivating it in the hopes that I may see it, in time, as a neat little tree. Its foliage certainly turns a most brilliant and fiery red.

For those who are admirers of the horse chestnut—and who is not?—there are two Oriental species that are well worth growing, Æsculus indica and Æ. turbinata. The former is similar to our common horse chestnut, but, in the young stage, at least, is more graceful, while the petals are more reflexed and the panicle has not such a stiff appearance. A. turbinata is noted for the size of its leaves, which are often 16ins. long. I agree with Mr. Bean about the sturdy appearance of the young tree, but I do not agree about its inferiority, apart from size of leaf, nor do I find it slow growing.

There is one buddleia that is far too little grown, and that is B. Fallowiana, and the reason for its lack of popularity is hard to trace, for I find it a most excellent plant in every way. It is usually catalogued as the best white-flowered buddleia, but the flowers, lovely as they are, are to my mind of minor charm compared to its wonderful silvery grey foliage, which in the young stage is almost pure white. It is a graceful plant and not a coarse grower, and I find it absolutely hardy. I have never seen a large plant or even a description of one, but I can imagine it certainly equalling B. alternifolia for grace and charm. It also has the advantage of flowering in a young state.

FEIJOA SELLOWIANA.

Clethra Delavayi is the next on my list and provided that your soil is lime-free, this is a magnificent addition to our flowering shrubs. After the soft C. arborea, the lily of the valley tree, C. Delavayi has the finest racemes of white bells, but unlike C. arborea, it is absolutely hardy and thrives in any good loam; indeed, so hardy is it, that I do not even find it necessary to grow it in a shady position. It makes rather a stiff growth and I do not find it a particularly rapid grower.

Dipelta floribunda has been figured and mentioned in THE GARDEN several times, but it still is not sufficiently seen, for, when in May and June, it is laden with its fragrant pale-pink funnel-shaped flowers, so like a weigela in shape and form, it is one of the most lovely of all shrubs, for not only is it floriferous but has a graceful arching shape.

Exochordas Giraldii, grandiflora, Wilsoni, are probably all forms of the same species and it is difficult to tell t'other from which; not that that matters, for these quick-growing shrubs are all excellent and are certainly among the best white-flowered shrubs that we possess. The flowers are flattish and are carried on short racemes. They like sun and a good depth of soil and I find that they do not take kindly to transplanting. They are probably best grown in

PLAGIANTHUS LYALLII, ONE OF THE MOST BEAUTIFUL OF ALL SUMMER-FLOWERING SHRUBS.

Digitized by Google

a group of four or five, with a dark background to show off their multitude of white flowers.

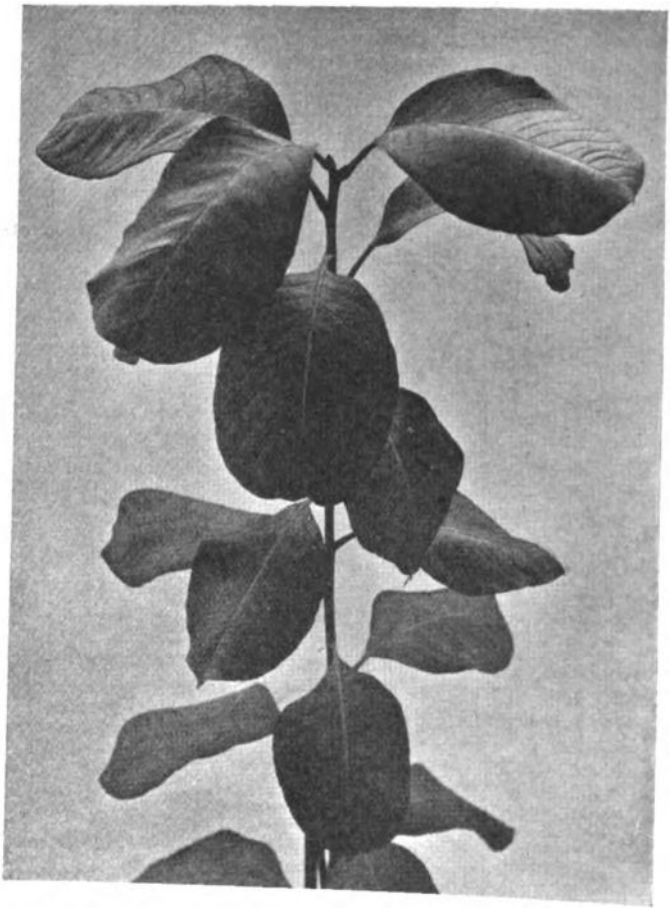
I include Feijoa Sellowiana with considerable hesitation, for it is only hardy in sheltered districts, but it is so attractive that, in the west at any rate, it should be more often seen. In shape the flower is something like a fuchsia, with a blob of blood-red stamens and heavily reflexed petals, white inside and purplish-crimson outside, while the leaves are leathery and evergreen. It can either be grown as a bushy shrub or can be pruned to form a small tree.

There is a Chinese shrub with flowers like an abelia, called Kolkwitzia amabilis that should have more attention paid to it, for it is rare to find such a twiggy and slender looking morsel with so many and such beautiful flowers. It never grows more than 5ft., but the twigs arch and droop and branch to such an extent that it will cover a considerable amount of space. The flowers are pink and are borne in pairs during May and June. I find it absolutely hardy, but it has a dislike of drought and should be planted in deep, moist loam.

Salix magnifica is, undoubtedly, the most remarkable of all willows—so much so, that I have planted it in a shrub border where space is valuable; but here is a willow with leaves anything up to 10ins. long—although mine, so far, have just touched 8ins.—oval in shape and with a delicious blue tinge about them, a striking contrast to the mahogany stem. It does not appear to grow very large, and even in the wild state has not been found over 20ft. in height. I have not seen the catkins, but the male are described as 4ins. to 7ins. long, and the female up to 11ins. It is perfectly hardy.

I must add yet another white-flowered shrub, Styrax Wilsoni. This grows to a height of 6ft., is twiggy and graceful in growth and has an abundance of nodding, pure white blossoms.

There is a guelder rose called Viburnum macrocephalum, which I personally consider the best of all sterile viburnums. This is owing to the lovely shade of green apparent when the flowers first open, turning after a day or so to the snowiest of white. Unfortunately it is not so hardy as it might be, but as a cool house wall shrub it cannot be bettered.



THE HANDSOME FOLIAGE OF SALIX MAGNIFICA.

VIBURNUM MACROCEPHALUM AT THE EDINBURGH BOTANIC GARDEN.

There is a certain number of shrubs and small trees that colour well in the autumn that are increasing in popularity, but not sufficiently fast for the worth of the plants. Among them are Euonymus alatus, that never grows out of hand and turns the most blazing scarlet-crimson in autumn and Rhus Cotinus, particularly the purple form, atropurpurea, that keeps its dark purplish foliage throughout the season. Another valuable autumn colourer that is not sufficiently often seen is Cercidyphyllum japonicum, which grows to a large shrub or a small tree, according to pruning. Its foliage dies off various shades of yellow or orange. As it is a graceful grower, it looks particularly well close to water. None of these presents any difficulty in cultivation, but the rhus should be planted in soil on the dry side.

Many forms of the mountain ash, Pyrus Aucuparia, are especially valuable for berrying. A new variety called munda sub-arachnoides is one of the best, with brilliant crimson berries; while of older varieties I should choose asplenifolia, fructo-luteo, with yellow fruits, and rubro-sanguineum, with deep coloured berries. These are all invaluable both in the shrub and in the wild garden and may be planted either in groups or as specimens.

Decaisnea Fargesii is another Asiatic introduction, but in this case it is striking for its blue contorted fruits. The leaves are pinnate and from 2ft. to 3ft. long, which makes it a handsome foliaged shrub. It grows to about 7ft., but although hardy, it should be sheltered from winds.

I must not leave Malus Sargenti out of this list, for here we have all the beauty of the crab, its mass of flowers and fruit, condensed into a bush that never exceeds 6ft. and of a bushy habit, with branches that sweep the ground. Here is an invaluable subject where space is a consideration. Others which are larger growers of the Malus section are Pyrus Eleyi, one of the darkest in flower, fruit and foliage; Scheidekeri, like a magnified floribunda and marvellously profuse in large blossoms.

Digitized by Google

There is a holly that has escaped the notice of most gardeners and that is Ilex corallina. It was sent to me as Desfontainea spinosa, but I have been the gainer for the error. The leaves are very like those of desfontainea, but in I. corallina they are alternate, while in the former they are opposite. So far I have not seen either the flower or the fruit, but it has one great advantage in that it is one of the quickest growing evergreens I have seen. I have planted it by a south wall, as it is supposed to be tenderish—a statement which I do not believe—and it has grown 3ft. or more in a year. The foliage is extremely handsome and if the fruit is as good I should place it as the most handsome of all hollies.

There are two forms of Plagianthus Lyallii, one more downy than the other and called glabrata. For beauty they are the same and with thin, paper-like white flowers. I should place them among the dozen best shrubs. They have stood 22° in my garden and suffered no damage, although it is said that they are liable to damage by severe frost. No garden should be without this shrub.

With the exception of Feijoa all the shrubs mentioned are suitable for a garden with an ordinary exposure. Gardeners differ about their choice of autumn or spring planting of shrubs and trees. Personally, I prefer the spring, provided that it is not left too late, principally for the reason that in the past season or two the ground has been difficult to work in the autumn. The longer I garden the more certain I am that many casualties in newly planted trees and shrubs are caused by too deep planting.

E. H. M. Cox.

THE FIFTY BEST ROCK PLANTS

BY DR. R. LLOYD PRAEGER.

(*Continued from page* 53).

LET us now take the opposite case—that of the rock gardener who likes the best, is willing to give time and and take trouble with difficult things, has enterprise and an eye for daintiness as well as showiness, and is not disheartened by occasional funerals. It is necessary to point out that in this case also a plant's value is not to be judged by its being rare or difficult: common or the reverse, its intrinsic beauty and interest are what matters:

Allium azureum
Acæna Novæ-Zealandiæ
Androsace helvetica, glacialis
Æthionema spp.
Astrantia minor
Aquilegia alpina
Anemone sulphurea
Armeria cæspitosa
Artemisia glacialis
Asperula suberosa

CELMISIA CORIACEA, ONE OF THE BEST OF THE NEW ZEALAND DAISIES.

Campanula excisa
  Raineri
  Zoysii
Calceolaria polyrrhiza
Celmisia spp.
Cassiope fastigiata, selaginoides
Conandron ramondioides
Corydalis cheilanthifolia
Cyananthus lobatus
Cypripedium spectabile
Daphne petræa
Diapensia lapponica
Dianthus neglectus
  Freynii
Epigæa repens
Eritrichium nanum
Gentiana bavarica
  Farreri
  verna
Gaultheria trichophylla
Geranium argenteum
Haberlea rhodopensis
Hypericum cuneatum
Iris cristata
  gracilipes
Lewisia Howellii
Linum alpinum
Lithospermum rosmarinifolium
Loiseleuria procumbens
Mertensia echioides, etc.
Meconopsis spp.
Mimulus primuloides, etc.
Moneses uniflora
Myosotidium nobile
Omphalodes Luciliæ
Onosma Bourgæi
  cassium
Ourisia coccinea
Oxalis adenophylla
  magellanica
Pentstemon rupicolus
  heterophyllus
Phyteuma comosum
Potentilla nitida
Primula Littoniana
  Winteri
Ramondia spp.
Raoulia australis
Saxifraga Boydii
  Burseriana major
  diapensioides
  Irvingii
  lilacina
  longifolia
  Cotyledon vars.
  Fortunei
Sedum trifidum
  primuloides
  spathulifolium purpureum
Sempervivum arachnoideum
  hirtum
Schizocodon soldanelloides
Shortia uniflora
Silene Hookeri
Soldanella spp.
Sisyrinchium grandiflorum
Tanakæa radicans
Townsendia Willcoxiana
Viola cenisia
Wahlenbergia spp.

The above list will probably strike the reader as even more unsatisfactory than the previous one, because the choice is more difficult, and because in this case individual preference makes itself more strongly felt. But I have endeavoured to meet criticism by leaving the choice open in some genera where there are several "best" species, by choosing widely—from crevice plants to bog plants, and very easy to very difficult—and by increasing the prescribed fifty to over seventy. Nevertheless, I do not hope to satisfy anybody, and can hear a chorus of objections—acænas and sempervivums are too common to be included in the "best" list; conandron and lithospermum rosmarinifolium are too tender; myosotidium and Cypripedium spectabile are too large; the cassiopes, androsaces and daphne named, and also eritrichium, diapensia, moneses, schizocodon, townsendia, are too difficult. Well, if this list does not please you, go and make your own! There is plenty of choice, and yours will be quite as good as mine.

But THE GARDEN is always particularly considerate towards the beginner and the amateur, and if I left the matter there the Editor might come down on me, so a further effort is necessary. After all, what most rock gardeners will consider the best plants will be those which combine as far as possible the good qualities of both lists—beauty, elegance and brightness (if

Digitized by Google

that be the reverse of dulness), variety of flowering time, a good constitution, and ease of propagation. We cannot hope to get all these qualities in all the plants—some are naturally more showy or more easy than others—but the following list (the last with which I shall trouble the reader) is an attempt to arrive at a good working selection, taking all things into consideration; and it may be looked on as one of several lists that might be compiled of the "Fifty Best Rock Plants":

Acæna Novæ Zealandiæ
Achillea Kellereri
Acantholimon venustum
Æthionema pulchellum
Anemone blanda scythinica
Androsace carnea
Arenaria montana
Astrantia minor
Asperula suberosa
Aubrietia Dr. Mules
Campanula pulloides
Raineri
garganica
Celmisia coriacea
Coronilla cappadocica
Corydalis cheilanthifolia
Cyananthus lobatus
Cypripedium spectabile
Daphne Cneorum
Dianthus neglectus

A FINE ACHILLEA HYBRID, A. KELLERERI.

The list runs to nearly sixty species instead of fifty, but I really cannot see my way to reducing it any further; it would be a great deal easier and more satisfactory to extend it.

Only one further word is required. I take it that any "Fifty Best" list, to give satisfaction, must display variety as well as quality. Therefore a large number of genera have been included; and though there may be a dozen kabschia or silver saxifrages which may rank among the best of rock plants, only a few are named, in order to allow of the inclusion of other plants whose charm is of a different order.

NOVELTIES IN HALF-HARDY ANNUALS

MANY of the most popular of bedding plants belong to the half-hardy section of annuals, and it is among these that plant breeders are always busily engaged fixing new breaks, selecting and re-selecting specially fine and distinct varieties, and evolving or developing new strains.

The popularity of ten-week stocks and China asters entitles them to foremost consideration, and, excellent as these have been for very many years, the latest novelties and developments are, in a special sense, achievements of which the raisers may be justly proud, and the whole gardening public may welcome them with gratitude.

A race called "Super Dreadnought" stock is particularly good, its tall growth, usually averaging and sometimes exceeding 2½ft., with many fine spreading branches covered with large, well doubled flowers. Varieties of this new ten-week stock which will give every satisfaction are: Neptune, a rich dark blue; Picture, cream flushed with pink, after the manner of the cream pink sweet peas; and numerous others of lavender, scarlet, crimson and yellow shades.

Another good strain of large-flowering, tall-growing stocks is the Monarch, which also embraces all the best shades of colour to be found in the tribe.

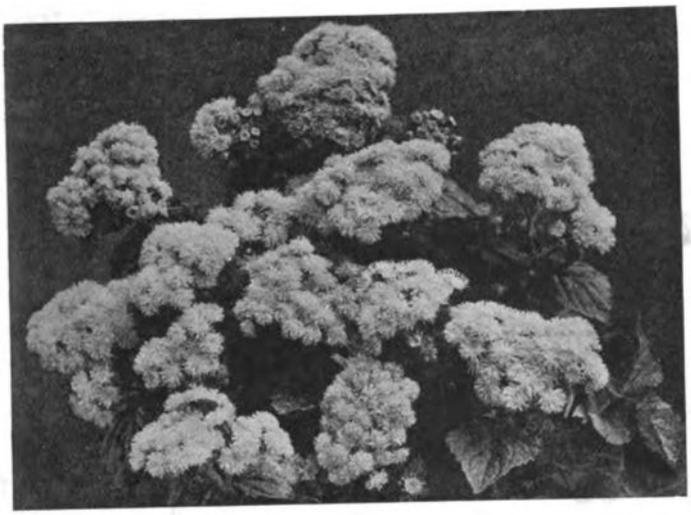
John Bright is not actually a new stock, for it has been known and grown by the keen amateur florists to be found among Lancashire cotton weavers for well over a century; but it has at last been placed in commerce by a Manchester seed firm, and, having rigorously re-selected its very best form, it has been shown with distinction at Southport Show, and also gained an R.H.S. award in London. Spikes exhibited carried well over 12ins. of expanded bloom, its colour being a brilliant crimson.

Of asters—which, by the way, very few people recognise by the more accurate name of callistephus—the most noteworthy development is the Sunshine aster, for this gives us a flower of distinctly new and highly decorative character. The blossom has a cushion-like centre of closely packed quilled florets surrounded by a collar of slightly larger florets which fade away to white at the edges. Around this is the ring of petals which are slender, long and curling, giving the flower a shaggy but very elegant appearance. The plant branches freely, throwing its flowers well out on long, wiry stalks. The colours (in mixture) embrace many delightful shades, such as porcelain pink, silvery lavender, delicate mauve, as well as brighter pinks, rich reds, purples and pure white. Aster Sunshine is a gem among flowers for cutting.

For a double aster of fine large size and lasting qualities, useful alike for vases in the home and for the exhibition stage, the new Californian Giant is unsurpassed; it is really a very remarkable advancement on our best races, such as the Comet and Ostrich Plume. It is available in two distinct shades of pink, a light blue and a rich full purple. Aster growers, whatever their particular purpose may be, will find the Californian Giant of very great service.

The giant dahlia-flowered zinnias made a favourable impression when first they were staged in this country, although the flower is one which will never appeal strongly to everyone. Some consider the hard outline and severe formality of zinnias unnatural and displeasing, but there are those—and they are many—who dote on the perfect regularity with which the

Digitized by Google



AGERATUM LITTLE BLUE CLOUD ATTRACTIVE WITH ITS DIMINUTIVE COMPACT HABIT.

flower is built and to whom the unusually vivid, solid and decisive colourings are sheer delight. These latter will find in the dahlia-flowered type an unstinted feast of enjoyment, and for most purposes the best plan is to sow the best mixture of seeds, because, although named varieties are offered to colour, it is at present considerably uncertain how many variations from the particular colour desired may be discovered when the plants bloom. In this respect each successive season will doubtless witness considerable improvement, for both in seed farms and in amateurs' gardens the rich orange variety called Golden State, the glowing Crimson Monarch and the white Polar Bear were seen by the writer during 1925 in a great deal purer state than they were from the previous year's seed.

We have another new development in giant-flowered zinnias which is labelled "Achievement"—this, however, being the sixth word in an irritatingly clumsy appellation. It is enough to make any ordinary mortal decide to grow something else when told that, in order to make sure of getting the right thing, he must ask his seedsman for Zinnia elegans double robusta grandiflora Achievement; and it is a mistake to shackle a good thing with such an encumbrance of idle words.

The individual feature of Achievement is that, while the flowers are of large size they are relieved of heaviness by the elegant rolling of the petals into tubes giving the blooms a cactus-like appearance. The mixed colours embrace coppery orange, lilac, salmon, rose and other rich shades.

It is highly gratifying to note real progress in the improvement of cosmos, a flower of real elegance but hitherto marred by rather serious faults. In the first place, it has been the customary habit of the plants to grow into big spreading bushes bearing but few flowers until the end of summer, and then throwing up a quantity of buds to get killed by frosts before they can open; and another fault has been that the prevailing shade of colour is mauve, more or less leaning toward a flat-toned puce or magenta. Advice has been freely given that seeds should be sown in autumn to ensure early flowering: sound enough advice for those only who have ample glass accommodation. The Fairy Queen strain and others of similar character, usually catalogued as early-flowering cosmeas, have overcome these objections. The plants are comparatively dwarf, sturdy and compact, and they begin to bloom much earlier than the old types; while one may secure a real rich crimson in Crimson King, a lively rose pink in Rose Queen, and a clean pure white in White Queen. The same colours are available in so-called double forms, but at present the degree of doubling varies to some extent. The one cultural tip that may well be given in regard to cosmos is to withhold rich manure, restrict root-run, and tread the soil very firmly. It is a plant which grows extremely well in harsh stony or chalky soil, and I have seen it doing quite well in richer soil when young plants in pots have been merely plunged in the soil, allowing only a few roots to find their way through the drainage holes or over the edges of the pots.

Several catalogues this season make a feature of Didiscus cœruleus, and, although this is not really a new plant, but more correctly a resurrection, it deserves notice because it is certainly not well known, or it would undoubtedly be very extensively grown. Even the trade seems a little uncertain concerning its realities, for, while some correctly class it with half-hardy annuals, others describe it as a grand new hardy annual. The plant enjoys the common name of the lace-flower, probably on account of its extreme elegance and the beauty of its pattern or disposition of its blossoms at the head of a slender but strong stalk. The individual pips are narrow tubes of varying length flattening into a five-lobed corolla, from the centre of which pin-head stamens protrude. The foliage, too, is elegantly cut and subdivided—perhaps another reason for its common name. The colour of the flowers is a delicate, sweetly pretty shade of pale blue, softer than plumbago blue. It likes warmth, a dry position, and is otherwise of perfectly easy culture. Its height varies from a foot to 18ins., and, in addition to being a grand bedding subject, it makes a capital, decorative pot plant.

Ageratum Little Blue Cloud annexed the affections of many who saw it when it received its award of merit last year. If only it will retain uniformity of its diminutive, compact habit from seed, it will be a treasure; but there is an "if" about this. The prudent will rogue it very carefully, select the very best, cut the plants over early and propagate from cuttings as is customary with edging lobelias. It is a plant which one feels justified in anticipating will in reasonable time become sufficiently well fixed to come practically true from seed.

Mention of lobelias reminds me that a particularly well fixed strain of the popular variety Mrs. Clibran is now being distributed, and it is so conspicuously an improvement upon the ordinary stocks that, with seed of this "improved" Mrs. Clibran there is really no practical necessity to propagate it from cuttings.

New and improved bedding petunias are quite numerous, and whether one requires a perfectly uniform bed in some pure, rich, solid colour or prefers the riotous colours of some huge trumpet-flowered strain with margins frilled and lacerated almost in imitation of endive leaves, his wants may be readily supplied. It would be invidious to single out any particular strains or varieties for special mention, because others as good would be omitted, and the reader has only to consult a good catalogue to find the different types and colours clearly described.

In nicotianas (tobacco plants) Crimson King gives us the really bright flower, free from dull plum or purplish tint, we have long desired; and another treasure is available in the newest hybrid strains of gilia, which maintain the charming elegance in foliage and flower of Gilia coronopifolia and extend the colour range to embrace palest of pinks, creams and sulphur yellows, and fuller, richer shades of apricot, terra cotta and rose pink.

This article would assume unreasonable length before it could barely mention the new breaks and decided improvement in salpiglossis, verbenas, the tagetes family and a whole host of other pretty and useful annuals; but those mentioned will provide ample choice for many gardens. A. J. MACSELF.

MODERN TYPES OF BEDDING ASTERS.

NOTES OF THE WEEK

COREOPSIS.

THIS is a genus of showy annuals and perennials which are extremely valuable as border plants, while they are in great demand as cut flowers. The annuals are sometimes quoted under the name of calliopsis and the perennials as coreopsis, of which C. grandiflora is a noteworthy example. This is a beautiful decorative subject for the herbaceous border, its large, rich, deep golden yellow flowers being produced in quantity during the summer and autumn months. The plant attains a height of about 3ft. and no doubt the best results are obtained by raising a batch annually from seeds. C. grandiflora is such a glorious border plant that it pays to grow it well and, moreover, it is a decided acquisition to a dozen vases of perennials at the local show, in addition to the quantity of flowers that may be cut for house decoration. Most attractive is a bed of this plant and all it requires is a deep root run and a liberal dressing of partly decayed manure. Perry's variety of C. grandiflora is semi-double, rich golden yellow and free flowering.

Another pretty perennial is C. lanceolata, which grows about 2ft. high and produces bright yellow flowers 2ins. to 3ins. across. It is one of the best perennials. A useful plant is C. verticillata of perennial habit, 1ft. or 2ft. in height. The bright yellow flowers are smaller than those of C. grandiflora and are produced on more slender stems. C. verticillata can be increased by division in spring or autumn and also by seeds sown in June or July. A dwarf-growing species known as C. rosea has small, rosy-white flowers, but this plant is rarely met with.

They are of easy culture and will thrive in almost any situation, consequently they are often seen in town gardens, where many subjects would dwindle and die. I have used C. Drummondii and others for bedding and they have proved most valuable, the flowering period extending over many weeks. C. Drummondii has large golden yellow flowers with chestnut-brown centres and it should be sown where it is intended to bloom.

CC. atrosanguinea, tinctoria and Golden Crown are all good annuals, but there are others and several seed catalogues quote a wonderful selection. For a small garden the special mixtures are advised and they can be utilised for beds or bold patches in the border. The seeds should be sown in March or April and severe thinning is necessary to get the best results. Many annuals never attain their full stature and beauty, because they are not allowed enough space to develop to their fullest extent.—T. W. B.

COREOPSIS GRANDIFLORA.

ON SALVIAS.

SURELY there never was a genus of plants with so many relatives as the salvia. Wherever you turn, whether it be the herb garden, the parterre, the mixed border or the greenhouse, there is pretty certain to be found a salvia. They are grown for all sorts of reasons. For seasoning meat, for the brilliant colours of their flowers, for the beautiful coloured bracts adorning the tips of their stems, for the form or scent of their leaves.

For the most part they are very easy to grow—raised either from seed or cuttings. Some of them are not hardy enough to withstand the rigours of our winters out of doors, but they require but little shelter and warmth to keep them alive till more genial days come round again.

Such varieties as Salvia patens, with its marvellous deep blue flowers of velvety texture; and S. splendens, with its gaudy scarlet coat, are almost too well known to call for comment. Robinson considers the former "without question one of the best plants in cultivation." The other, originating from Brazil in tropical South America, requires some protection during winter. There are many admirable varieties of this plant. The hybridists, especially those of France and Germany, have done much to improve the strain.

Apart from these two aristocrats of the sage family there are a great number of poorer relatives, each of which has something to recommend it to the lover of flowers.

What is this plant on the staging of the greenhouse, with soft rich green leaves which, when touched, give off a perfume of pineapple? A salvia (S. rutilans). The dark crimson-scarlet flowers produced in late autumn add a further charm to this interesting plant. If allowed to grow unchecked in the bed of a greenhouse, these plants will attain quite luxuriant proportions, but they will not flower nearly so well as when they are cramped in a small pot.

THE OLD-FASHIONED SALVIA SCLAREA.

What is that patch of purple over there in the mixed border? A salvia (S. horminum). This commonly goes by the name of "Bluebeard," on account of the purplish blue bracts which freely crown each stem. A hardy annual, it usually sows itself freely, preferring a poor dry soil. At times the bracts are pinkish and in this case the inconspicuous flowers are pink to match, instead of blue.

What are these large flat tufts of silvery white leaves which clothe the ground so nicely? A salvia (S. argentea). It comes to us from southern Europe and finds a welcome in our gardens as a carpet plant, for the sake of its decorative leaves. It is often referred to as "Silvery Clary."

The old-fashioned Clary (S. Sclarea) has long been in cultivation in our cottage gardens by reason of the herb wine brewed from it. Culpepper tells how "this is also in some counties known as Clear-eye, the seed put into the eyes clears them from motes and such like things gotten within the lids to offend them, also clears them from white and red spots." The wild clary was even more esteemed than the cultivated variety. This, according to the same authority, was "most blasphemously called Christ's Eye" (Oculus Christi).

While on the subject of herbs we must just see what there is to be said about our common sage (S. officinalis). A large bush of this, when in full flower, is surely beautiful enough, with its lavender-coloured flowers and grey leaves to take its place in the mixed border. It is said to follow the fortunes of the house, to wither when Fortune turns her face away and to revive when better days return. All the herbalists seem to be in agreement that sage "maketh the hayre black." The Arabians of old set such store by sage that they summed up its merits in the saying, "How can a man die who grows sage in his garden?" This, as Lady Rosalind Northcote ("The Book of Herbs") suggests, may be the origin of the English saying,

"He that would live for aye
Must eat Sage in May."

It appears that toads have a great liking for sage, and Turner in his herbal gives directions for planting rue together with the sage "to prevent the poison which may be in it by toads frequenting amongst it, but Rue being amongst it they will not come near it."

Though but a very few of the salvias have been mentioned in this short note, enough has been said to give an idea of the variety there is to be found in this large family. Robinson, indeed, gives more than forty different salvias in "The English Flower Garden," and it is pretty safe to say that his list will be by no means complete. The collector's zeal would surely be sorely taxed in an attempt to make a collection of all of them.—EDWARD CAHEN.

CALAMINTHAS.

OPINIONS regarding the relative value and beauty of plants vary greatly; but the writer was greatly surprised the other day, just after seeing one of the calaminthas in quite a beautiful plant, that a most excellent work devoted to hardy flowers tells us that the "only species worth growing among the Calaminthas is C. glabella." I think a good many readers will disagree with this dictum if they are at all acquainted with either Calamintha alpina or C. grandiflora. In any case, I do not think that C. glabella is in commerce, and there is no reference to it in one of our newest and most exhaustive works on alpine flowers, while both of the others are in the hands of the trade and are

Digitized by Google

good enough for inclusion in almost any border or good rock garden. There is not a very great difference between the two in general habit. Both are rather decumbent but C. grandiflora is the larger in growth, while it has also finer and better coloured flowers than C. alpina. These calaminthas belong to the natural order of Labiatæ, and from their branching, decumbent or prostrate stems bear a great number of flowers. In the case of C. alpina these are of a pleasing violet with a white lip; while C. grandiflora has them altogether of a brighter tone of violet, more nearly approaching pink, and has more aromatic foliage than the other.

One great advantage possessed by these calaminthas is that they flower for a very long time in summer, and another is that they are of easy culture under ordinary border or rock garden conditions if planted in a sunny place. Propagation is by division, cuttings or seeds, and planting is best done in autumn or spring.—S. ARNOTT.

SOME INTERESTING RUBI FROM CANADA.

IT has been my privilege to collect and grow some of the uncommon but, nevertheless, equally attractive rubi from Canada. We find here that plants raised from seed grow far better than collected plants, and most varieties seem all the better for hard pruning in the dormant season. Rubus parviflorus, commonly called in Canada the capberry, is similar to Rubus odoratus in habit, but differs in the colour of the flower, being snow white with crinkled petals. It is most attractive when planted in association with R. odoratus.

R. spectabilis (the salmon berry) is a tall grower with yellowish bark. It has large pink flowers, followed by most attractive yellow and red fruits. The latter are used by the Canadians for making jam.

R. triflorus is a dwarf variety, never higher than 18ins., with small white flowers and dull red berries.

R. pedatus is a dainty little trailing raspberry suitable for rockeries, where it can show off its light green leaves with small starry flowers to great advantage. Its great attraction lies in the fact that it fruits and flowers at the same time.

R. deliciosus, a spineless variety forming a very large bush, is very charming when planted in an isolated position.

R. arcticus, another dwarf variety, growing at high altitudes, is not very attractive.

A FINE COLONY OF THE MADEIRA ORCHID AT KEW.

R. leucodermis, the whitewash bramble, has white flowers followed by dull black fruits. It should be planted with a background of evergreen shrubs, as then in winter its white, leafless stems are shown off to advantage.—R. MOORE, *Thorpe Hall Gardens.*

THE MADEIRA ORCHID.

WITH a few exceptions, hardy orchids cannot be termed a success in gardens generally; but the one quoted above is often seen in a flourishing condition, especially in some parts of Scotland. It is known as Orchis foliosa and is a native of Madeira, from whence it was introduced many years ago. This fine plant attains a height from 18ins. to 3ft., and the spikes appear in May, while the flowers are usually at their best in June and July, according to the season. The unspotted leaves are long and broad and the flowers a rich purplish red, are densely set on a stout spike which does not require a stake.

It has proved hardy in Great Britain, and one is rather surprised that such a fine subject is not more often met with, particularly in gardens where plants of merit are a special feature. It will pay for generous treatment, enjoying a rich rooting medium; but perhaps the most important factor is that the site must be more or less moist at all seasons. In spite of this, however, good drainage is essential, and a stagnant position must be avoided. I have seen fine clumps growing in bogs, also in other parts of the garden; but where the roots could be afforded plenty of water during the summer months. A spot shaded from the midday sun is advised, and the soil should consist of peat or sweet leaf-mould, to which is added a little loam and a fair sprinkling of sharp sand.

Frequent disturbance is not desirable, but where clumps have become unduly crowded division can be resorted to in the spring, and this is also a suitable time to plant this delightful orchis. When planting or making a new colony, it always pays to secure strong roots; the cost is slightly more than ordinary alpines, but it is well worth the outlay.—T. W. B.

THE SPINELESS CANADIAN BLACKBERRY, RUBUS DELICIOSUS.

NOTES FROM SWITZERLAND.

IN a Christmas letter from my friend George Flemwell, who for some years has made Lugano his headquarters, there are, among other references to plants seen during his wanderings from April to September, several which he thinks may interest certain readers of THE GARDEN.

Throughout the whole of the itinerary made by Mr. and Mrs. Flemwell, he seems to have "worked very hard among the flowers and insects"—most of this work I take to mean painting. "The Via Mala is evidently the home *par excellence* of white Gentiana asclepiadea—there was more white than blue, and very fine it was. In the Via Mala, too, and on one rock, was a potentilla which I cannot place with certainty. I enclose dried samples of it." This is P. caulescens, *L.* At first I did not recognise it, but was helped by finding specimens in my herbarium which I had gathered also in the Via Mala in 1900.

From two places in the Engandine, whose names are better not disclosed, he came across "a small colony of hybrid Gentiana lutea purpurea, probably the G. Charpentieri of such local botanists as Caviezel, but where I saw it growing it was in a gradation of forms, lutea being the dominant parent as regards colour. There were no brown forms, and the only traces of purpurea in the flowers were a slightly warmer yellow colouring (nearing to apricot), a few spots in several of the hybrids, and the more cup-like shape of the flowers. G. lutea (type) was there, but dwarfer than one finds it in Vaud;

Digitized by Google

G. purpurea was a short way off. The more distinctive of the hybrids are most attractive and the milky, illusive shade of warmish yellow is very fascinating. The plant is sturdy, erect and finely foliaged. It would prove a real acquisition to any rock garden. . . . Nature here has shown the way to hardening hybridists, and profitable experiments with purpurea and lutea might well be carried out. This hybrid is quite distinct from the flavida variety of purpurea."

During the Conference at Locarno Mr. and Mrs. Flemwell " were in the thick of it at the Palace Hotel. On Mrs. Chamberlain's birthday, the day of the famous excursion on the 'Orange Blossom,' when virtually the Pact was agreed upon, the Management of the Palace presented her with a fine bunch of alpine rhododendron (ferrugineum), gathered expressly by peasants in the Maggia Valley. Mark you; October 9th!"

This rhododendron is not often found in blossom after the end of April, even at its highest stations of 8,500ft. to 8,800ft. in the Valais. In Tessin it descends into the plain by Lago Maggiore, as, *e.g.*, in Val Maggia, which is twenty-five miles long and noted for its rich vegetation, rocky scenery and pretty villages. The village of Cevio, which is fifteen miles up the valley, is only 1,370ft. above sea level, the lake itself being 636ft., or little more than half the altitude of the Lake of Geneva. It is quite possible that late autumn flowering of the " Rose des Alpes " is more frequent in such low altitudes and in turbaries in woods of the central Swiss plateau, where it is a glacier relic, than in the higher mountains, where the summer season is so short.—H. S. THOMPSON.

NOVELTIES IN SWEET PEAS

(*Continued from page* 43.)

QUEEN OF ROUMANIA (W. J. Unwin). — Although a soft and dainty shade, this novelty is exquisitely rich. The catalogued description reads " At first glance, it appears to be a very warm and rich cream-pink, but closer examination reveals it as a very soft, light salmon-cerise, suffused and flushed on a deep cream ground. The colouring intensifies towards the centres of standard and wings." Like another of Mr. Unwin's 1926 novelties, it is a seedling from a W. J. Unwin cross, having the same size, perfect shape and robust habit as its parent. It is one of the prettiest peas I have seen, and I think its popularity is assured.

ROYAL PINK (R. Bolton and Son).—As exhibited I should judge this pea to be nearer an orange-salmon than a pink, and I see by my notes that I have described it as a much lighter George Shawyer, but I have not seen it growing. The raiser's colour description reads " Pure pink ground, illumined with rich shrimp and further enriched with a veining of deep rose. A perfect model of the twentieth century sweet pea."

RYBURGH CRIMSON (G. Stark and Son).—A large crimson, with a distinct trace of orange, giving a brilliant effect to the flower. The raiser tells us it is " a fine pea for exhibition."

RYBURGH CERISE (G. Stark and Son).—I have already mentioned this pea in my remarks on one or two other novelties. A large, rosy cerise with a standard of brighter hue. It is " a strong grower, and splendid for artificial light," to quote its official description.

SKY (W. Atlee Burpee and Co.).—The colour of this novelty falls somewhere between that of Wembley and Mrs. Tom Jones, and is described as a light but clear and bright silvery lavender-blue, practically a self, although there is a tendency for the wings to become slightly deeper than the standard.

SYBIL HENSHAW (W. J. Unwin).—From what I have seen of this pea I fully expect it to become one of the most popular crimsons, especially with exhibitors. The colour is near that of Crimson King, if anything slightly deeper and with a metallic sheen overlaying the standard. It is more vigorous and stronger in the stem than Crimson King, with bold, massive-looking flowers. It is what the exhibitor terms a " weighty " pea. Undoubtedly the largest and most vigorous sunproof crimson self to date.

THE FAVOURITE (F. C. Woodcock).—A very large flowered, dark-seeded white, much after the style of Constance Hinton and Giant White. I do not know enough about it to pass any opinion on its merit as compared with the first named. Several whites have been introduced and " boomed " since Dr. Hinton gave us Constance Hinton, but it still retains its position in public esteem as the best and most satisfactory pea for general purposes. Mr. Woodcock's own opinion of this novelty is reflected in the name he has chosen, and I have sufficient confidence in his judgment to add that it is certainly well worthy of a trial.

TWINKLES (W. J. Unwin).—Many of my readers will have tried Lady Gay, which Mr. Unwin placed on the market last season. Twinkles is marked in the same curious manner, and is the first seedling introduced which crosses with Lady Gay have produced. The ground colour is a rich cream, and the flushings, veinings and picotee edge of bright scarlet. The reverse of the standards is very heavily marked with scarlet, giving an arresting and attractive appearance to the bunch. I, personally, much prefer it to its parent, Lady Gay, and the name Twinkles is well chosen. All who admire something really uncommon and distinct in sweet peas should try it. Exhibitors should give it good culture and confine the growth to one " leader " per plant.

VENUS (J. Stevenson).—I believe Venus will prove to be the best of the Cecily, Fair Lady, Mrs. Arnold Hitchcock group. Its colouring is very pleasing, cream-pink suffused salmon. As yet I cannot endorse its raiser's opinion that " it will displace all other cream-pink varieties." This is rather a " tall order," for it has such peas as Mary Pickford, W. J. Unwin, Miss California and Magnet to contend with among cream-pinks. Without a doubt Venus is a very good pea, and should be grown by all admirers of the older peas Cecily, Mrs. A. Hitchcock, etc.

WHITE LADY (J. Stevenson).—Another white which Mr. Stevenson says " After repeated trials can, with confidence, be recommended as the best fixed white in cultivation." A better white-seeded pea than Edna May Improved, Florence Wright Improved or King White is really needed, and I hope White Lady will prove superior to them. The whites lag behind many of the other colour classes in real improvements, the white-seeded varieties seeming to deteriorate all too rapidly.

WISTARIA (W. J. Unwin).—Last on my list, but by no means least. This is one of the most delightful peas I have seen. Unfortunately, I have never had the chance to compare them side by side, but I believe Wistaria is somewhat after the colour of that other 1926 novelty Mermaid, but I judge the former to be slightly deeper and having the blue tone more pronounced. Its raiser rightly says " A really distinct and valuable novelty in the lavender class is somewhat of an achievement " and I think those whose taste condemns Wembley as too insipid and Austin Frederick Improved or R. F. Felton as too rosy, will probably find Wistaria near their ideal. " It is a bright blue-lavender, delightfully cool and clean, with no trace of harshness. The bright medium blue in its composition imparts a fresh, clean appearance, even to the old blooms." Add to these attributes great vigour, length of stem, lovely placement and a particularly sweet perfume, and you have a good idea of its sterling qualities.

Although I feel sure no startling advances will be registered by any 1925–26 sweet pea novelty, several appear to be real improvements, and if this proves nothing else, it indicates quite plainly that the sweet pea is far from being " played out " as regards potential improvements. Glancing over the list again, we cannot fail to notice the wide range of distinct colour over which they are spread, to say nothing of distinct shades. We find six cream-pinks or creamy-pink flushes, four deep cerises, three pinks, three in various shades of orange-salmon, two blues, two whites, two fancies, two blue-lavenders, two crimsons, one white ground flush, one mauve, one cream, one scarlet, one ivory, one blush-pink and one bronzy deep blue.

As I have already stated, I have not had the pleasure of closely examining all the above novelties, but I have seen nearly all. These would be my own choice if my collection of 1925–26 novelties were restricted to a dozen kinds: Black Bess, Ivory Picture, 2LO, Magnet, Mary Pickford, Mermaid, Mrs. Horace Wright, Peggy, Queen of Roumania, Sybil Henshaw, Venus and Wistaria, for they have particularly impressed me. C. H. A. S.

SOME NEW VARIETIES OF VEGETABLES

BY EDWIN BECKETT.

THE Editor has suggested that notes on some of the newer varieties of vegetables that have come into commerce during the past year or two may be of some assistance to growers who may not yet have come into touch with them, but before proceeding with them there is a word or two of explanation necessary. The variety that may be quite new to the owner of a small garden or allotment may only be comparatively so to the cultivator of a larger area, and to the big grower, especially the one keenly interested in exhibition work, may even be termed old, so that, when considering the varieties that will be set before you, it must be understood that you must judge them from your own particular viewpoint. These notes also, I may add, are the outcome of a general survey of some of the items that have stood out markedly in our culture at Aldenham. Lastly, it is necessary once again to reiterate the old statement that a variety that does well in one particular neighbourhood may not prove such a success in another, so that it will be well for those who would try any of these successes to have a trial season first in order to note their results on his particular soil.

The first item that I have noted down is a variety of cabbage for spring sowing named Velocity. Not only has this proved a very fine variety with us, but I have heard excellent reports from various quarters. It is a quick-maturing sort; in fact, if left standing where sown and thinning adopted to allow it room for growth, it can be cut about twelve weeks after sowing, and thus will prove valuable for substituting the autumn-sown varieties should they, as they sometimes do, fail badly. The quality of this new introduction is also excellent, it is one that everybody should try. Another brassica novelty which has many good points is the cabbage, Carter's Herald.

Next I want to refer to three beans, two French and one broad variety. French bean Magpie is a very fine introduction originally brought from France and cultivated here to adapt it to our climatic and other conditions; it is a really first-class item. Long and large in pod, the flavour and quality is very fine, but over and above these factors are its additional adjuncts of heavy cropping and its adaptability to forcing. It never seems to fail to crop, even when other varieties disappoint, and it continues to produce for a longer period than most others.

Nain Parisien, a variety we obtained from France, is another fine thing, with large pods, of early habit and excellent flavour, very suitable for forcing and highly productive.

The broad bean is The Sutton, a remarkable new introduction in the year 1922. Dwarf in habit, only running about a foot in height it requires no staking, but, being of branching habit, it carries a large crop of pods, each containing about four or five white seeds, which, when cooked and served well, prove of delicious flavour. Such a prolific variety, that gives so little trouble, deserves to be tried by every grower, and especially the one with but little space at his command.

Beetroots always look more or less alike, but a very distinct appearance was borne by beet New Intermediate, which is an oval-shaped root, midway between a long and a globe form. It is of excellent texture and flavour, and from its shape a very desirable one from the cook's point of view, while the gardener likes it because it is a variety that matures early.

Broccoli varieties, of one form or another, are an enormous group, form seeming to cross with form most readily, but for a really distinct variety I would select Nine Star broccoli. The origin of this is somewhat wrapped in mystery, but it was a surprise when it was sent to me for trial, and I readily recommend this broccoli to all growers. It carries heads like a small cauliflower, as many as nine the first season, and appears to be quite a perennial form, standing well, though necessarily it will have a limited existence from a production point of view, and the greater number of years it grows on and throws sprouts after the previous season's cuttings, the smaller must be expected the sprouts, but it will certainly be an effective yielder for three or four years.

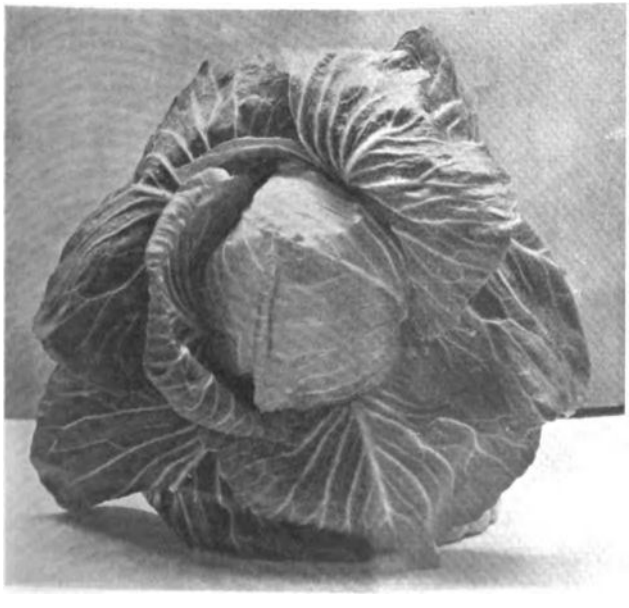
SUTTON'S SPROUT FILLBASKET.

Another brassica that has taken my fancy is the new Brussel Sprout Fillbasket, a variety of tall-growing character, well protected at the top, and carrying a large crop of large-sized sprouts, fine in quality and of very close, firm texture, avoiding the opening habit that many varieties fail with.

Two fine capsicums that were sent to me for growing last year, and of which I believe much will be heard in the future, are Ruby King and Golden King. For the exhibition table they will, in my opinion, prove almost ideal.

Maize, again, is rather out of the ordinary run, but I must not pass over the claims of an excellent variety of the sweet or Indian corn. This vegetable is a very important one with the connoisseurs of the United States, and will, I believe, come into big demand as a vegetable on this side in time. For those who want to grow the best my advice is to get, if possible, Maize Early Malcolm, as it is of first-class quality.

An onion that is not frequently met with and deserves reintroduction almost as a novelty is Premier, which so consistently produces fine large, heavy, solid bulbs of excellent shape and texture, and proves such a really good keeping maincrop variety, while as an



CABBAGE CARTER'S HERALD.

Digitized by Google

exhibition onion it is second to none. We now come to another vegetable that too many small growers leave alone as being unprofitable and as requiring good staking, the vegetable pea, and to those who argue thus I would say try Giant Stride. This only grows 2ft. tall, and as these small plants carry, under proper cultivation, as many as thirty pods at a time, this alone speaks volumes for their yield; and another extraordinary thing is that these pods are nearly as large as those of Quite Content, and hold from eight to ten good-sized seeds within each pod, and these of excellent quality when cooked, so that quality and quantity, combined with dwarf stature and quick-maturing capabilities, makes this a more than useful new introduction for everybody. Another excellent pea, this time a maincrop variety, is Chancelot, which only reaches about 3ft., but is a first quality pea, of excellent yield and good healthy constitution, and one that has greatly impressed me with its general utility claims.

An unknown, or comparatively unknown, tuberous vegetable must not be overlooked, and that is Oxalis tuberosa. Those who have seen any of the exhibits I have staged of recent times may recall a very attractive-looking rose red tuber, something like a very large red Chinese artichoke. As a cooked vegetable and properly prepared for table, this demands attention. A native of South America, it seems quite happy in our climate; in fact, it only appears to form its tubers properly after the tops have been cut by frost, and although a tropical denizen, yet does not appear to appreciate forcing under glass. As an exhibition vegetable for big mixed collections it certainly ought to rank as a prime favourite.

Potato introductions are many, year by year, but there are four that stand out prominently in my favour for their general utility and quality. Arran Victory, a round variety, with purple skin and fine white flesh, immune from wart disease, is not only a pretty show potato, but is also excellent for cooking purposes and a good cropper. Arran Comrade, immune, round shaped, white, second early, is a very heavy cropper, of high table quality, and the large number of even-sized, shapely tubers produced per root makes this stand out very distinctly among its fellows, and renders it a fine exhibition variety. The Bishop, a pretty variety when flowering with its attractive rose-pink flowers, is certainly one of the very best, if not indeed the best, white kidney-shaped maincrop potatoes of the day. Most consistent in its excellent cropping, with fine, even, shapely tubers which make it a very good exhibition variety, its cooking qualities are all that can be desired by the most critical. This also is an immune variety. The last to note here is that pretty variety Di-Vernon, a heavy cropping first-early variety, immune from wart disease. It is a fine, shapely kidney, the eyes of which are beautifully marked with purple stains, and on the show table looks remarkably effective. But its appearance is not all its merit, for as a "cooker" it is first class.

A radish that calls for mention is Rosy Gem, one of the quickest I know in growth, and of excellent texture and flavour. It is a pretty root, oval in shape and delicately tinged rosy pink, and for forcing, general work, table and show stand, will take a lot of beating.

An outstanding tomato of heavy-cropping capabilities is Everyday, and for all purposes this should rapidly become a great favourite. It is a fine rich red in colour, of medium size, of splendid flavour, and has a fine, thin skin.

Turnip Elstree Early is another root product with which, as its name denotes, I am intimately connected, and it will suffice to say that those who try this, especially for early forcing work, will not, in my opinion, be disappointed.

The last item that calls for attention is the garden swede, a vegetable that is rapidly coming to the fore, owing to the big improvement in the modern strain. This item stands the ravages of severe weather far better than the turnip, and thus is decidedly useful for maintaining the supplies of this form of vegetable food.

There have been, of course, many other worthy new introductions during the past year or two that could well be mentioned did space permit, but I think that in the foregoing I have dealt with those of premier importance.

THE DUKE CHERRIES

BY E. A. BUNYARD.

THE group of cherries known as Royales in France and as Dukes in this country form a very distinct class. They are most probably hybrids between the wild gean or mazzard, Prunus Avium, and the sour cherry, P. Cerasus, or perhaps in some cases the prototype of the Morello, called by some P. amarasca, has played a part.

There are many evidences of hybrid origin in this family, defective pollen, an intermediate habit of growth, the bitterness of the Morello or sour cherry being tempered by the other parent to an attractive astringency. Furthermore, they all show the compact upright growth which makes them so desirable for garden culture, as they form naturally vase-shaped trees which require but little pruning.

It is difficult to understand why these cherries are not more commonly grown, for, to the fastidious palate, they stand alone in softness of flesh and for their attractive blend of sweet and sour, plus that slight astringency which can only be compared to that of an old claret.

There are no cherries so digestible or so clean on the palate as these, and M. Paderewski, as eminent an epicure as an artist, places them, as I do myself, first of all cherries.

A selection which would cover a period from June to end of August and, with the help of a north wall, even later, should include May Duke, Archduke, Royal Duke, Ronald's Late Duke and Late Duke.

THE ROYAL DUKE CHERRY.

May Duke is the best known of the family, and on a warm wall can be ripened in most years by mid-June; it is also much used for forcing. The flavour is excellent *when fully ripe*, a point which needs emphasis in a fruit like the cherry, which colours before it is full-grown.

Archduke follows in mid-July from the open ground; the red flesh is jelly-like and of a remarkably fine flavour. This is a very old variety which has long history, and may even have existed in Pliny's time, a point of interest to those who like a little literary-historical flavour mingled with their gardening.

Royal Duke, coming in mid- to end-July, is, in my estimation, the most delicious of all cherries, either raw or cooked. The flesh is rather more yellow than red, transparent, and extremely well balanced in flavour. Were it a wine one would read in the merchant's catalogue," round, full and velvety."

For bottling, if any can be spared, it is to the cherries as the Carlsbad plum to the French prune. Candour, however, compels the admission that it is not a prolific bearer, but, like many of the best things, requires some degree of patient expectancy.

Digitized by Google

Ronald's Late Duke follows, and worthily maintains the ducal tradition. The large size and dark shining crimson colour make it as attractive without as it is within.

Late Duke comes into August to finish the season, and is distinct in its more heart-shaped form and pale yellow flesh, the latter coming as a surprise beneath the dark red skin.

The flavour is very rich and good, in fact almost equal to Royal Duke.

All these varieties do well as fans on walls, and are naturally suitable for vase-shaped dwarf trees and much more successful, by reason of their short pointed growth, for cordons than most cherries. Like all stone fruit, they require lime, and when established will appreciate rich manure.

It will be found that a small sprinkling of nitrate of soda just before blossoming time will markedly aid in setting fruit.

TOOLS AND THEIR SELECTION

IT is a surprising fact that, while one is constantly reading of the great value of thorough methods of cultivation as an aid to success, very little space is ever devoted to the selection of suitable implements for accomplishing this purpose. Many an amateur—to whom the tilling of a garden or allotment is just an interesting hobby for spare time and not undertaken for pecuniary gain—has had foisted upon him at some time or other an entirely unserviceable and badly finished article usually with the excuse that it is a particularly cheap line. "Cheap" tools are often expensive in the long run and should be avoided, for constant replacements have to be made. It has been said that it is a poor workman who blames his tools, but it must be remembered that there are good and bad tools, and often the quality of the implements will play a large part in the successful completion of any task.

I suppose one of the first, and certainly one of the most important, tools to be used in the making and upkeep of the average garden is the spade, and it is a matter of surprise to notice the hundreds of cheap lines of the "tin-can" order that are displayed, and evidently sold, by many local ironmongers. The badly fitted stocks, roughly burred rivets and sharp-edged straps usually found on these bargains are calculated to tear and blister the toughest skin, while the blade is often so soft and pliable that, in all but the lightest of soils, it is worse than useless. During the war some of the keenest brains in the country were employed in experimental work producing special steels for special purposes and, as we all know, many of the wartime products depended entirely upon a minimum of weight and bulk combined with a maximum of hardness and strength. It is pleasant to record that, with the cessation of hostilities, some of the firms engaged in this work immediately set out to apply the valuable knowledge and experience thus gained to the production of high-grade articles for use in peaceful occupations. As a result of this the manufacture of tools, and particularly of horticultural tools, has been very materially improved, and it is now easy to become the possessor of a really well balanced, well finished and efficient spade or fork. In making the selection do not make the mistake of thinking that the bigger the tool the quicker the ground can be covered. Often it is the reverse, for it must be remembered that these huge tools are proportionately heavier and usually tend to make a long spell of digging a very wearisome affair. For general use a No. 1 size is, perhaps, the most convenient, the blade usually being about 7ins. by 11½ins. When making the purchase carefully examine the whole tool for possible flaws and make sure that the handle is snugly and firmly fitted to the socket straps. Pay special attention to the blade, both back and front. This should be perfectly smooth or a rusty tool will very quickly follow. Select the lightest possible specimen which is consistent with strength and utility, for it will be found that the difference of a half-pound in the weight of the tool will mean practically a ton less lifted in the course of an average day's digging. In the writer's opinion it is far better to pay a few shillings more and get a branded article made by a firm who specialise in the manufacture of horticultural implements. The "Neverbend" spades and forks made by Messrs. Spear and Jackson, the "Brades" tools made by Messrs. William Hunt and Sons or the "Rustless Steel" spade made by the Hardy Patent Pick Company are all excellent brands which can be relied upon to give good service and which can be easily obtained from most good-class stores. In buying a digging fork the same care and attention should be given to the points enumerated above, and a little thought should be given as to the nature of the soil in which it is to be used. A four-pronged fork will generally be found more serviceable for use in very heavy soils, while the larger forks with fine prongs can be more safely relied upon for use in light soils.

The hoe is, perhaps, the next tool in importance, and here again we meet with many specimens offered for sale which are comparatively worthless. Broadly speaking, hoes may be divided into two types: the Dutch hoe, which is worked on the push principle, in front of and away from the worker; and the draw hoe, which, as its name implies, is worked towards the operator. The former is of no great service in any but the lightest and not too stony soils, while the latter can be used on either light or heavy soils, and is also particularly valuable for earthing up rows of peas, potatoes, etc. They can be obtained in various sizes and patterns, but for general use either a 5in. or 6in. blade will be found most convenient. Choose a type with a good forged steel blade fixed to the socket by means of a solid bar bent in the shape of a swan's neck. This allows of the blade being worked at that angle which will give the user most power over the tool. It should be firmly mounted on a stout ash handle in such a manner that no play is left between the sides of the socket and the wood.

(To be continued.)

CORRESPONDENCE

PIERIS IN SCOTLAND.

SIR,—I was interested in your notes in the issue of January 16th last on Trees and Shrubs in Scotland. You specially mention those interesting and delightful ericaceous plants the pieris or andromedas, as they are perhaps best known. Our experience with several varieties mentioned has been quite happy, as the better known P. floribunda grows exceedingly well here and rarely fails to flower profusely. P. japonica also does well, but the variety that grows most vigorously is formosa. This sort has probably the largest flowers and foliage of the group, the young growths in early summer being also very attractive. P. formosa is not generally recommended for cold districts, but I sometimes say that if plants of somewhat doubtful hardiness succeed with us they will do in most places in Scotland—for, although Coodham is only five miles from the Ayrshire coast, we sit fairly high, while our subsoil is a cold blue clay. Naturally, when planting any choice subjects we have got to give them some kindly mixture to start them; but, with the exception of guarding the plants from cutting winds in their younger stages, that is about all the coddling allowed. To the pieris we generally give a good percentage of peat, sand and leaf-mould, incorporating it with the natural soil, and have found the plants to respond quickly. I have rarely found the frost hurt them much, although this winter we had 26 degrees several mornings in succession. I quite agree that the pieris are among the most beautiful of our flowering shrubs and regret that they are not more generally planted.

We had a very fine effect with P. floribunda and Rhododendron præcox, both flowering simultaneously.—JAMES MCGRAN, *Coodham, Kilmarnock.*

SEEDLING BIRCHES.

SIR,—This garden has been showing us the ease with which birch trees may be grown from seed. Less than four years ago we added to the garden by taking in half an acre of croft and turning it into flower beds and borders. The borders are stone edged and the paths gravel and ever since they have been made we are constantly finding self-sown birch seedlings between the stones edging the paths and in the rock garden. They are carefully taken up and planted in the new fence which runs the whole length of the garden and which seemed to swallow unlimited numbers of plants and yet never be filled.

However, by this time the oldest plants are 5ft. and 6ft. high and crying out to be thinned drastically. This garden is very open and windswept and I longed for something to grow and form a hedge quickly. Now I look

Digitized by Google

like having one of birches, though they tail down from 6ft. at one end to 1ft. where the youngest seedlings are.

The parent birches are at the entrance to the garden, quite a distance from the stone-edged borders and there are no others within a mile. The soil here is rather heavy loam on clay, so I suppose the seeds find it more homelike among the stones and gravel, for scarcely ever does one come up in the open border. I am hoping the young trees will be quite a feature before long, although they are in one straight row, if only the cattle in the neighbouring field will refrain from making a meal of the leading shoots.—E. BUXTON, *Burton-on-Trent*.

HYDRANGEA HORTENSIS ROSEA.

SIR,—In your Correspondence columns of December 19th, 1925, I note an article regarding "Colour Variation in Hydrangeas," in which Mr. Arthur J. Cobb, Reading, would like to know where plants of H. hortensis rosea can be procured.

I know of only one nursery in this country where I think this plant may be obtained. J. B. Pilkington, nurseryman, Portland, Oregon, lists in his catalogue three varieties of H. hortensis, which he designates as pink, blue and white. Whether one of these is rosea or not I cannot say. He would be glad to answer any enquiries regarding this and I hope Mr. Cobb may be able to find just what he is looking for.—M. IVAN DUNLOP, *Los Angeles, California*.

NERINE BOWDENI.

SIR,—As no one else has answered Sir Herbert Maxwell's query in THE GARDEN of December 26th, 1925, *re* Nerine Bowdeni, my cousinly pride makes me reply that the Mr. Bowden, who brought the N. Bowdeni to England, is Athelstan Hall Cornish-Bowden, now Surveyor-General of Cape Colony; it must have been about twenty years ago he made an expedition with natives and dug up a lot of these bulbs and had them sent home to his mother in Newton Abbot and she sent them to a nurseryman who then placed them on the market.—ELIZABETH F. CORNISH-BOWDEN, *Devon*.

TWO ROCK GARDEN ANNUALS.

SIR,—In THE GARDEN of January 2nd, one writer mentions Ionopsidium acaule. I am sure that this minute and pretty annual is not known at all well or we should see it far more often than is at present the case. A native of Portugal and rarely growing above 2ins. high, it is very useful for planting, or rather, sowing in crevices of crazy paving, as mentioned in the article above referred to and for odd corners in the rock garden.

May I be allowed to plead the case of yet another little known annual, Portulaca grandiflora. This, although catalogued as half-hardy, is quite hardy in the south. I have seen it growing in profusion on a sandy border. The colours of the flowers consist mainly of shades of purple and red and although vivid, these striking colours never clash. A patch of this plant seen in full sun is really dazzling and anyone possessing a warm corner where a plant 6ins. to 8ins. is wanted, would be well advised to try this annual.—N. D. H.

LONICERA FRAGRANTISSIMA.

SIR,—In your Correspondence columns in THE GARDEN for January 23rd, I see Mr. Harris has failed in blooming the above honeysuckle.

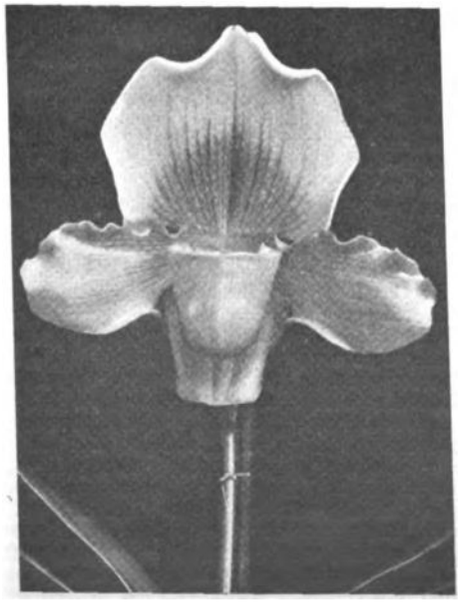
We find it quite easy here; it is planted on a sheltered south wall. This seems most essential to protect it against the winds and frosts. In March we prune it very hard and at the same time mulch it with old farmyard manure. It blooms on its new wood, after the manner of L. Standishii and its flowering season is very long, commencing in November and continuing until the end of February. I think the hard pruning is very necessary.—R. MOORE, *Thorpe Hall*.

SIR,—I am rather surprised that the plant referred to by Mr. Harris, Lydney, Glos., fails to bloom, because here at Castleford, Chepstow, this fragrant lonicera flowers annually, some years better than others. Castleford is also in the county of Glos., and some eight miles from Lydney.

It would be interesting to know how the plant is pruned, because we leave our specimen alone, except for an occasional thinning out of old wood. It is growing at the base of a wall facing south-west and is more or less shaded by large elm trees.—T. W. BRISCOE.

THE TURN OF THE YEAR

THE atmosphere of spring could almost be sensed in the R.H.S. Hall on January 26th last, on the occasion of the ordinary fortnightly meeting of the Royal Horticultural Society. Already colour is appearing in the garden week by week, whites, yellows and blues predominating, and the exhibits in turn take on a more lively aspect. Bright patches of colour scattered here and there throughout the Hall were much admired, both for their intrinsic beauty and from the fact that they serve to remind us that the turn of the year has really and truly come. Greenhouse flowers were, naturally, plentiful and of a miscellaneous nature, and comprised a fine exhibit of forced bulbous flowers by Messrs. Sutton and Sons, an extensive and magnificent display of cyclamen by Messrs. Blackmore and Langdon; while irises and primulas came from Raynes Park, and a small but praiseworthy collection of roses from Mr. Elisha Hicks. Carnations were again in evidence, and their gay colours added not a little to the brightness of the Hall. The alpine flowers are now beginning to waken from their winter's sleep and push up their noses in response to milder weather conditions, and many of the rock exhibits held much of interest to all alpine enthusiasts. All alpines would seem to weave a strange fascination round one at this time. They are the very essence of the season with their miniature and compact cloaks of fresh green topped by their blossoms, which appear too delicate to stand the rigours and vagaries of an English spring. Nevertheless, they are here, and from now onwards until April and May they will be present as one of the integral parts of these shows in ever increasing numbers. The other exhibits were of a miscellaneous nature. Sundries again were prominent, and among them was an exhibit, arranged by Messrs. Malby and Co., the horticultural photographers, which calls for special mention. Of recent years garden photography has undergone almost revolutionary changes. We have arrived at a new era, the day of the camera. All will agree that a pictorial representation of some subject is worth as much, if not more, than pages of verbal description, especially when the illustration is almost true to life. That we have reached such perfection in floral photography there is no doubt. Messrs. Malby's colour reproductions almost seem to live on the photographic plate. The colours are there and, what is still more important, the subjects are portrayed in a natural style. There is nothing stiff, formal or unreal in the reproduction. The coloured plates of general garden scenes were as excellent as those of individual subjects and showed great skill in execution, with a faithfulness to detail combined with a true colour record for which the artist justly deserves a word of praise. The black and white reproductions showed equal care and skill in their execution, and served to testify as to the educational value of all photographic work. Messrs. Malby have already established their name in the horticultural world, and their exhibit of work will doubtless enhance their reputation as one of the leading horticultural photographers in this country.



ONE OF THE MOST DISTINCT OF ALL CYPRIPEDIUMS, C. SIR TREVOR.

The most effective and striking of the floral groups was set up by Messrs. Sutton and Sons. It was composed of a splendid collection of well grown forced bulbs in bowls. Hyacinths, tulips and a few irises, lilies of the valley and narcissi were shown. The hyacinths were particularly fine and very fragrant, the best varieties being Prepared White, Christmas Pink, Pink Plume and Prepared Cynthella Yellow. Good bowls of the tulips Duc van Thol, Mon. Tresor, and the attractive deep purple Iris reticulata were much admired.

A large and imposing group of cyclamen was exhibited by Messrs. Blackmore and Langdon. The plants were very robust, and each carried a number of well shaped blooms. The arrangement of the stand was most effective. The varieties Scarlet King, a glowing crimson scarlet; Brilliant, a rich carmine; and Salmon King, with its silvered foliage, formed vivid patches of colour. Bath Beauty was a good new cyclamen with enormous flowers of salmon pink; and Mrs. Buckston, a soft rosy pink, was the only frilled variety exhibited. A few cyclamen were also shown among a collection of carnations and various greenhouse plants by Messrs. Stuart Low and Co. An interesting crested cyclamen was noted on this stand. Cherry Ripe and Pink Pearl were their two finest varieties, the former being one of the brightest of any of salmon red cyclamen.

Mr. Elisha Hicks had a small but attractive group of forced roses. The colour of a few of the varieties was pale, owing to the forcing,

Digitized by Google

but the texture was perfect. Mrs. Herbert Stevens, Lady Hillingdon, Mme. E. Herriot and Padre were in good form. Messrs. L. R. Russell exhibited some good greenhouse plants and shrubs, including azaleas, camellias and Pycnostachys Dawei, that striking perennial herb with intense blue flower spikes which received an award of merit a year ago. Anemones and rhododendrons came from Mr. R. Gill. Mr. C. Engelmann had some fine specimens of Rouge, Nero, Rosalia—some of his newest carnations. Late-keeping apple varieties were exhibited by Messrs. Bunyard and Messrs. J. Cheal. Garden sundries and tools were shown by a number of firms, and many artists exhibited floral paintings.

Among the alpines, Messrs. Tucker's exhibit was remarkable for its form and Messrs. Waterer's for content. Messrs. Tucker made a rock garden of two grey mounds planted with Burseriana saxifrages enclosing a hollow set with cyclamen, Primula Juliæ and P. Winteri. The Burseriana on one hillock was the natural form "Tridentina," on the other, for comparison, the firm's own hybrid Brookside, which, unlike most hybrid saxifrages, has certain advantages over the type, for the petals are well overlapped and, however widely open, never show the daylight between them, and they have inherited some of the solidity of the parent S. Paulinæ. Messrs. Waterer showed a collection of bulbous irises, I. reticulata, Histrio and histrioides with their splashed and painted signal patch, and the rare Heldreichii, scented like Cyclamen europæum and remarkable for the velvety quality of its pale violet, darkening to a deep patch on the falls. The ghostly white Narcissus monophyllum and those two exquisite and unexpected freaks of nature, N. minimus and N. cyclamineus, with the beautiful but neglected crocuses, CC. Sieberi, Tomasinianus and Cloth of Gold.

Messrs. Cutbush grouped their spring bulbs very naturally and pleasantly among early-flowering shrubs—Andromeda polifolia, Cydonia Maulei, C. Simonsi and Erica carnea. They showed the fine large-flowered form of hepatica, Galanthus Elwesii and the rare Iris Tauri.

Messrs. F. G. Wood showed the old, but still appreciated, double primroses, Narcissus minor and nanus, and several crocus species.

Among the numerous exhibits of orchids, Messrs. Charlesworth and Co. had a very attractive group, mostly composed of hybrids which had been raised to provide many-flowered spikes during the winter months, the best example being Odontoglossum Dora with a branched spike of eighty-nine flowers. O. Wilckeanum bore a spike of thirty-four large flowers, and there were several promising odontonias in which the influence of Miltonia vexillaria is visible in the increased size of the labellum. Silver-gilt Banksian medal.

Silver Banksian medals were awarded to Messrs. Stuart Low and Co., whose group was mainly composed of species, including such interesting plants as Cypripedium Chamberlainianum, Chysis aurea, Brassovola glauca and Dendrochilum Cobbianum with several pendulous racemes.

A similar award was given to Messrs. J. and A. McBean, Cooksbridge, Sussex, for an exhibit of cymbidium and odontoglossum hybrids, the former including C. rosefieldiense with large flowers of emerald green colour, and the latter a heavily blotched variety of O. majesticum.

Messrs. Sanders, St. Albans, were equally rewarded for their group of rare species and popular hybrids, the last mentioned including well grown plants of Cypripedium Maudiæ, various cymbidiums of the insigne section, and a large-flowering variety of Brasso-Cattleya fulgens.

Messrs. Cowan and Co., Southgate, also received a silver Banksian medal for their group of elegant cypripediums, which embraced the first-class certificate variety of C. Perseus and C. Vashtii. The centre was filled with the bright yellow Oncidium splendidum, while in front was the rare Odontoglossum Duvivierianum and O. harvengtense, both natural hybrids.

Messrs. Armstrong and Brown, Tunbridge Wells, had a small but, nevertheless, select exhibit of cypripediums, novelties being seen in C. Gladys, with a purple flushed dorsal sepal, and in C. Pothan, with roundly formed segments. A feature was Lælio-Cattleya Schroederæ with a seven-flowered spike. Bronze Banksian medal.

Other exhibitors included Messrs. A. J. Keeling and Sons, Bradford, who staged several attractive cypripediums; Mr. H. Dixon, Wandsworth Common, who showed various species and hybrids, including a vigorous plant of Cypripedium Rossettii; and Messrs. Black and Flory, Slough, whose exhibit contained the new Cypripedium Sir J. M. Barrie, as well as the Langley variety of Cypripedium Golden Wren.

THE FINE EXHIBIT OF CYCLAMEN STAGED BY MESSRS. BLACKMORE AND LANGDON

Among the amateurs' exhibits, mention may be made of Cattleya Harrisoniana, staged by Mr. S. J. Hawes, Eltham Road, Lee; Cypripedium Memoria H. J. Elwes, with unusually heavy spotting, staged by Mr. G. F. Moore, Bourton-on-the-Water; and Cypripedium Cappa Magna, a richly coloured flower, shown by Mr. J. J. Joicey, Witley, Surrey.

NEW AND RARE PLANTS.

AWARD OF MERIT.

STRELITZIA KEWENSIS.—This is a hybrid between S. Reginæ or S. angusta and shows characteristics intermediate between the parents. The flowers are borne vertically from the horizontal spathe and are of a pale almost watery yellow somewhat resembling those of S. Reginæ, but the small hooded petal resembles the other parent. The flowers are decidedly inferior in attraction to those of either parent. Shown by the Director, Royal Botanic Gardens, Kew.

ORCHIDS.

CYPRIPEDIUM SIR TREVOR (Casella × Christopher).—One of the most distinct and charming of all the cypripediums. The large flower is of model formation, the dorsal sepal porcelain white on the upper two-thirds of its area, the base being light greenish yellow, a colour also seen on the broadly developed petals, which are undulated on the upper margin; the labellum is yellowish. A special feature is the entire absence of spotting in any of the segments. Silver Lindley medal and first-class certificate. Shown by Mr. G. F. Moore, V.M.H, Chardwar, Bourton-on-the-Water (gardener, Mr. Page).

ODONTIODA COLINGE VAR. ROSEMARY (Odontoglossum crispum × Odontioda Coronation).—This elegant hybrid bore an erect spike of fourteen large flowers of crimson red colour, the sepals and petals having a narrow rose-tinted margin, the labellum white, with a red blotch near the yellow crest. Shown by Mr. J. J. Bolton, Claygate, Surrey (gardener Mr. S. Lyne). First-class certificate.

MILTONIA LYCÆNA.—The large flowers of this garden-raised hybrid have the petals flushed with crimson on their basal half, while the labellum is stained with a lighter tint of the same colour. Staged by Messrs. Charlesworth and Co. First-class certificate.

ODONTIODA GWENDOLINE, STAMPERLAND VAR. (Odontoglossum eximium × Odontioda Madeline).—This richly coloured hybrid carried a long spike of fourteen flowers of blood red colour in the sepals and petals the labellum being whitish, except for some red blotching on the central area. Shown by Mr. Robert Paterson, Cathcart, Glasgow. First-class certificate.

CYPRIPEDIUM PEERLESS (Curtisii Sanderæ × Holdenii).—A valuable addition to the "albino" section. The flower has the formation of the Curtisii parent to a large extent, the colour being light greenish with emerald green venation. Shown by Messrs. Armstrong and Brown, Tunbridge Wells. Award of merit.

SOPHRO-LÆLIO-CATTLEYA VULCAN VAR. PICOTEE (Lælio-Cattleya Dominiana × Sophro-Lælio-Cattleya Anzac).—An attractive hybrid which bore a spike of three flowers of a rich and bright purple, the labellum much more intensely coloured. Shown by Messrs. Black and Flory, Slough. Award of merit.

LÆLIO-CATTLEYA PIONEER (L.-C. Schulzeana × C. Trianæ).—A well cultivated plant, distinguished as the Manor House variety. The two spikes each bore five flowers of bright purplish colour. Shown by Mr. G. W. Bird, West Wickham, Kent. Cultural commendation.

ODONTOGLOSSUM DORA.—This attractive hybrid proves the value of odontoglossums for producing flowers during the dull winter months. The present example bore a branched spike of eighty-nine fully opened flowers. Shown by Messrs. Charlesworth and Co., Haywards Heath. Cultural commendation.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS

DELPHINIUMS.

THE second or third week in February, weather permitting, is a splendid period of the year to lift and replant delphiniums. Large plants which have been for some considerable time grown on the same border need occasionally to be supplied with feeding material to keep them in a vigorous and floriferous state as delphiniums enjoy and respond to generous treatment.

A few years ago we found it necessary to lift a number of fair-sized roots and trench the ground. The earth was dark in colour, and of a fine friable nature—to a certain depth—but somewhat exhausted. With this knowledge, and that of the plants having to be returned to the same border, we incorporated with the soil fairly large quantities of stable manure as the trenching proceeded, so that sufficient feeding would be available for the plants for some time to come.

As a rule, established delphinium plants lift with good balls—that is, their root system is fairly close and compact, and so a good quantity of soil clings to the roots. Therefore, with plants of this description no one need fear to lift and transplant, provided a reasonable amount of care is exercised in doing the work.

As soon as the ground was thoroughly trenched and manured the plants were set out, and, it is hardly necessary to add that they grew splendidly and altogether were much improved.—MIDLOTHIAN.

THE DAFFODIL SWEET PEA.

SEEDS of this variety were sown in a 4in. pot on February 9th last year. The plants were left to grow without pinching, yet fine young growths came away from near the base of each plant. The young growths appeared some time before the plants were placed in an 8in. pot. On May 2nd four of the plants had produced one vigorous (young) growth each, the other two plants had each two growths and the stems were 15ins. high. The old original unpinched stems were thin and poor looking compared with the others, while three of the old or original growths were blind. I therefore advocate the pinching of sweet pea plants, as the old growths or original stems, if left, eventually come to nothing. Two flowers were pulled from Daffodil on June 2nd. Four months generally elapses from seed sowing till flowering-time.—D. A.

PRICKING OUT ANTIRRHINUMS.

FOR pricking out seedlings from autumn-sown seed—a task for the early days of February—there is nothing to equal a frame-bed on a very mild hotbed. This secures just the soil warmth necessary to promote root activity and avoids a heated atmosphere. The notion that by bringing up plants from a cold frame into artificial heat they will be urged into good growth is imagination, unsupported by practical experience. The tendency of these days to ignore the utility of the hotbed is one rather deplorable instance of error of judgment on the part of modern horticulturists.

Where hotbeds are impossible the best plan will be to fill some boxes with gritty compost, prick out the seedlings from the frame and, having just warmed the soil in the boxes, place them on shelves in a cool, airy greenhouse kept at a steady temperature just above freezing at night. The open-ground seedlings will be best left until they show signs of making new growth in early spring, when they may be pricked out in a sheltered border, from whence they may be lifted and transplanted with a trowel into flowering quarters. Should the open-ground seedlings at any time during winter appear to be distressed, it is well to mulch the whole bed with sharp dry sand, allowing it almost to half bury the seedlings.

Of varieties we have a grand selection, and while some old favourites cannot be dispensed with, there are novelties of surpassing excellence which deserve to figure prominently in our bedding schemes.—M.

VEGETABLES

MUSHROOMS: A CHANCE CROP.

ONE meets with those who have attempted the culture of mushrooms under cover, whose common experience has been failure and whose success, when it did follow, was in the nature of a surprise. The growing of this welcome dish with quite a number of people is more in the nature of a lottery, and at the best is a chance crop. Even with this admission, the attempt is worth it, as, should entire failure be the result, the net loss is only that of the spawn, inasmuch as the manure can be brought into use for mixing with potting soil for certain plants or in the garden. It is not so easy, during the winter months, to generate and maintain the heat of a bed, under a shed, so necessary to the spread of the mycelium and growth of mushrooms, as it is from May onwards; and those who may have failed with a winter crop should now begin to put down beds for spawning. Undoubtedly, manure from corn-fed horses is the best, and this should be turned over from time to time to permit of rankness getting away, until the heat subsides to about 80° Fahr. after the bed has been prepared and well beaten down. Then spawn can be inserted and a coating of loam spread over the bed and made firm. The gardener who is inexperienced in the culture of mushrooms is generally imbued with the idea that artificial heat is the main factor in their production, and if he is not possessed of a house equipped with hot-water apparatus, he thinks it is of no use trying. This is altogether erroneous. Some years ago Mr. Edwin Beckett related an interview he once had with a most successful Scotch grower of mushrooms, who advised him in constructing a mushroom house to "thatch the house inside and endeavour at all times to maintain an atmosphere and temperature similar to that of a September night, when mushrooms grow so well in fields." It is the nearest approach to this warm, humid condition of the atmosphere that the grower should strive for, and in keeping up an even temperature. So many fail to appreciate the fact that great fluctuations of heat prevent the growth of the mycelium.—W. LINDERS LEA.

EARLY CAULIFLOWERS.

QUESTION.—Is it advisable to sow cauliflower seeds in heat early in the year?

Answer.—Yes, if very early produce is required.

Question.—How should seeds be sown and the resulting seedlings treated while under glass?

Answer.—The box in which the seeds are to be sown should be, approximately, 16ins. long, 12ins. wide and 4ins. deep. The soil most suitable is that which has been cut from an old pasture and heaped about six months. This is much better than old potting soils frequently used and the soil taken from the kitchen garden: both are bad—the former often teems with fungi spores and the latter is too sour and entirely lacking in fibre. To the good loam add some old mortar rubble and a small quantity of sweet leaf-soil quite free from bits of sticks. The box should be thoroughly drained and three-parts filled with the compost. Apply water, sow the seeds thinly and cover lightly with dry soil. Do not place squares of glass on the box, as this course often results in premature damping of the tender stems of the seedlings. Keep the box close to the roof-glass—approximately 18ins. from it—and transplant the seedlings in boxes 6ins. deep when the first rough leaf grows. Make holes in the soil 3ins. apart and drop the seedlings in almost up to their leaves. Very gently press a little soil into the holes and be careful as regards watering. Retain the plants in a cold frame for one month prior to planting out.

Question.—When is it quite safe to plant out?

Answer.—Mid-April in the south; the last week in that month in the north, if the plants are duly hardened.—GEO. GARNER.

SELF-BLANCHING CELERY.

SELF-BLANCHING celery is sown at the same time and treated in the same way at first as ordinary celery. The plants are put out in the garden on flat ground and left to grow there at will; rich, liberally manured land is required, and we find the best plants are obtained by burying manure in trenches and planting on top of this.

During the season no particular attention is required. In September it is better to cut off any offsets, broken leaves and the like, and then to tie the plants up loosely with raffia; this last is not a necessity. Plants which have to stay out all winter are, with us, hoed up, not for blanching, but against strong weather. The plants are robust, fleshy, well flavoured and quite good in all respects.—LANARKSHIRE.

MISCELLANEOUS

THE USE OF STIMULANTS.

QUESTION.—How soon in the New Year should stimulants be applied to plants in pots?

Answer.—If plants are growing in a stove temperature and the pots are well filled with roots, they may be fed almost all the year round; it is quite safe and beneficial to feed in February. If the plants are growing in a cooler temperature, and even if they have filled the pots with roots, it is wiser to wait until late in February before beginning to feed them than to begin a month earlier. As the sun gains power so do roots become stronger and more active.

Question.—Should newly potted plants be fed soon after that operation has taken place?

Answer.—No, a plant may possess many roots and be transferred to a larger pot, but in this condition it would be harmful to apply manure water or any kind of stimulant, because, first, the plant has just received some food in the form of new compost and does not require more for a time; and second, because such stimulants would be more than wasted—they would tend to sour the new soil. When the roots have permeated the new compost, apply extra food.

Question.—Is one strong dose of liquid manure better than two weak ones?

Answer.—No; two weak ones are best, and applied in two weeks instead of one single week. Liquid from organic manures should be the colour of brandy; soot water, clear; and proprietary manures according to the directions given with them.

Question.—When should stimulants be applied to outdoor crops?

Answer.—The best stage is that when the plants are beginning to make leaves and roots freely, and onwards.—HANTS.

(NOVELTY) PETUNIA
CARTERS Giant Flowered Dwarf

NOVELTIES OF THE YEAR TO SOW NOW.

BY APPOINTMENT

(VEGETABLE SECTION)

CABBAGE—CARTERS "HERALD."—Earliest variety for spring sowing. Per pkt., 1/6

CARROT — CARTERS "AUTUMN KING" STUMP - ROOTED.—Long, cylindrical, heavy stump-rooted carrot of large size. Per pkt., 1/6

PARSNIP—CARTERS NEW INTERMEDIATE. — Of Intermediate length without the slim long root. Per pkt., 1/-

PEA—CARTERS "MELTING MARROW."—A New Edible Podded Sugar Pea. Height 5ft. Pods of enormous length. Per pint, 2/6; per quart, 4/6

TOMATO—CARTERS "EPICURE."—Trusses average 8–10 fruits of very even size. Per pkt., 2/6 and 3/6

(FLOWER SECTION)

ANTIRRHINUM INTERMEDIATE "QUEEN MARY."—Medium - pink Intermediate. Per pkt., 1/- and 1/6

LUPINUS ARBOREUS—CARTERS "MAUVE QUEEN."—Clear mauve flowers, freely borne in well balanced spikes. Per pkt., 1/6

PRIMULA MALACOIDES — CARTERS "GOLDEN EYE."—A.M., R.H.S., 1925. Flowers pure white, circular in shape, centre marked by a zone of golden yellow. Per pkt., 2/6, 3/6 and 5/-

PENTSTEMON — CARTERS LARGE-FLOWERED "CARMINE QUEEN."—Flowers profusely first year from seed sown in February. 2½ft. Per pkt., 1/6

PETUNIA—CARTERS GIANT FLOWERED DWARF.—Large blooms; delicately weaved throats and undulating petals. Per pkt., 2/6 and 3/6

RANUNCULUS—CARTERS GIANT CAMELLIA FLOWERED—Flowers of perfect form, twice as large as previously known types. 18in. Per pkt., 1/6

13 SWEET PEA NOVELTIES

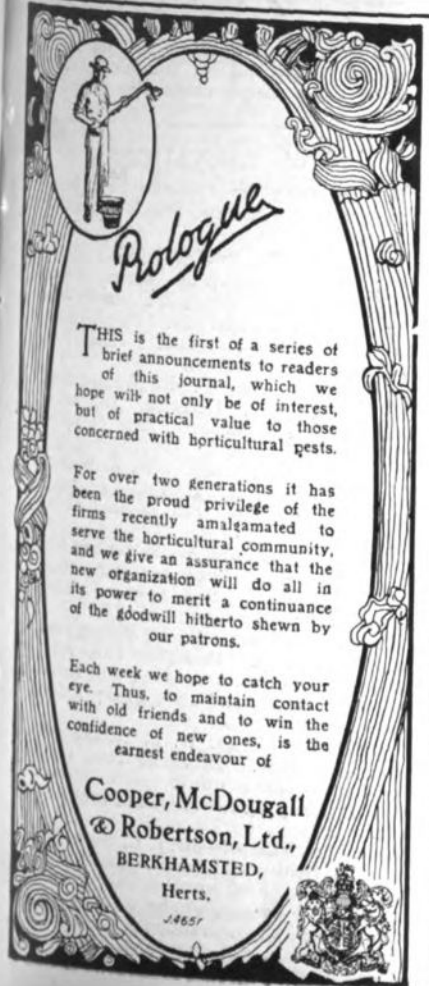
TESTED SEEDS

SEEDSMEN TO H.M. THE KING.
RAYNES PARK, LONDON, S.W. 20



Prologue

THIS is the first of a series of brief announcements to readers of this journal, which we hope will not only be of interest, but of practical value to those concerned with horticultural pests.

For over two generations it has been the proud privilege of the firms recently amalgamated to serve the horticultural community, and we give an assurance that the new organization will do all in its power to merit a continuance of the goodwill hitherto shewn by our patrons.

Each week we hope to catch your eye. Thus, to maintain contact with old friends and to win the confidence of new ones, is the earnest endeavour of

THE FRAGRANT ROSEMARY

WHAT a very neglected shrub is rosemary, when one stops to consider how beautiful a thing it is, and the many excellent ways in which it may be used in the garden. And yet I suppose rosemary has been in English gardens about as long as any plant that is not actually a native. I have just turned to Nicholson to find when it was introduced, and he also says nothing on that point, as he does of most plants—country of origin and date of introduction. He says, however, that there are three varieties of rosemary. The common green, the silver tipped and the gold tipped. But I can add three other sorts to Nicholson's three, *viz.*, the prostrate, the white flowered and Miss Jessop's Upright. Some years ago I saw Miss Jessop's Upright rosemary offered in the Daisy Hill catalogue and fell to the fascination of the name. There came a huge bush, some 4ft. high, which I planted against the south wall of my house and tried to believe was more upright than the rosemarys I had hitherto known. Rosemary Jessop is now well over 6ft. high, and maintains her uprightness of character. But she keeps me wondering, for upright, too, are most of the rosemarys that I see about, and those that I had grown before she came to me. Is there a *less* upright sort. I am never quite certain. I use much rosemary in garden operations at one time and another and often I have to buy the plant in, and then sometimes I get plants of a laxer, more wayward habit, and I am never quite sure whether this is inherent or due to environment.

The prostrate rosemary is a most distinct plant, but, unfortunately, it is by no means as hardy as the common type. I have tried it here several times, thirty miles north of London, and have lost it every time, though I believe that anywhere south of London it is fairly safe, and anywhere definitely south, perfectly safe. When it can be grown it is a delightful plant. The white-flowered rosemary I acquired last year, and so far it has not flowered here. I cannot think that it is as beautiful as the normal lavender-coloured type, but no doubt it will bring interest and the charm of novelty to the garden, just as the white lavender does, and this is a quality to welcome, yet to avoid overdoing. The same applies I think to the gold striped rosemary. This form I saw offered in Mr. Stormonth's fascinating catalogue and promptly bought. It arrived last summer, a perfectly normal little bush of grey green rosemary, but with infinite faith I planted it out, and with infinite faith waited and lo, this autumn it has spangled itself all over with buttercup gold, in irregular stripings along the leaf edges. The plant looks very gay and original, if a little fantastic, but I like it, and shall keep it. Now I want the silver-tipped rosemary that Nicholson mentions. Can anyone tell me where to get it.

Rosemary is a delightful shrub to train up a warm wall, and grown thus it will reach a height of 10ft. or 15ft. And it may also be planted as an isolated specimen in the mixed flower border, or grouped in big forests on warm banks and such like places. It makes a charming small informal hedge. Recently I saw it used with splendid effect in a Hampshire garden, massed in rectangular beds, about 6ft. by 12ft., flanking a long garden path of rather formal character. Lastly, rosemary is a delicious shrub to gather for the house; good, generous branches of it for simple arrangement by themselves, especially in winter.

The conventional soil to recommend for rosemary is a light, warm loam, and such soil, no doubt, it enjoys most, being a native of southern Europe. Yet here it has grown and flourished, a fine forest of it, for the last four or five years, on a bank of stiff, heavy clayey soil, facing east and most inhospitable in the matter of draughts and cutting winds. It has even come unscathed through the recent severe winter weather.

The easiest way to propagate rosemary is by cuttings. Branchlets pulled off with a heel, 9ins. to 12ins. long, stripped of leaves for half their length, and dibbled into soil, in a shady place in summer. The greatest joy of all the joys of rosemary I leave to the last—its smell, its delicious aromatic fragrance when crushed in the hand. And yet when one considers all its virtues, besides those which I have set forth, the plant is reputed to cure headaches and baldness—how seldom one meets the plant in real life. You will find great bushes of it occasionally in cottage gardens, and a planting here and there in gardens of greater pretention, but oh how rarely, compared with the bean and kidney shaped beds say of golden privet, that are so depressingly popular.—CLARENCE ELLIOTT, *Stevenage*.

THE FLAME NASTURTIUM

THERE are probably few of the older plants which have been the cause of so much despair among gardening enthusiasts as Tropæolum speciosum. At first treated as a greenhouse subject, it being considered too tender for outdoor culture, the flame nasturtium itself disposed of that idea by showing a decided partiality for life in the North, even in remote parts of Scotland, where it is now practically naturalised, to the sunnier South. But even with the fuller recognition of the fact that, although a Chilean species, this climber demands cool treatment, it still often displays much of that stubborn disinclination to prosper even in apparently ideal situations. Albeit, the flame nasturtium is a plant of such singular beauty that few keen gardeners ever abandon the hope of satisfying it, and, moreover, its very uncertainty is in itself a factor which stimulates the ambitious to succeed.

While it must be admitted that T. speciosum enjoys a cool vegetable soil, it is by nature a sun-lover, delighting to festoon with its ropes of crimson-scarlet flowers the outer and topmost branches of hollies, rhododendrons or other shrubs. At the same time, it likes its lower parts to be screened from the hottest sun, and there is little doubt but that failure to protect the young and tender shoots by some suitable shade has been the direct cause of much disappointment. It must often have been observed that once a plant has been sufficiently established to seed, a colony will soon be formed, but in almost every case it will be noticed that the successful seedlings are those which appear where they are almost hidden in their earlier stages by other plants. Here, for example, we have a group of Azalea Anthony Koster, whose branches, throughout the later summer, are thronged by the brilliant garlands of the flame nasturtium; but, while seedlings from these seldom appear in the open parts of the border close at hand, they come up in quantity among adjacent masses of Daphne Cneorum, Mitraria coccinea, and even under the heavy shade of a large bush of Pieris formosa.

Any attempt to establish T. speciosum should be undertaken in the late spring, after growth has commenced, and it is safer to put the plants out from pots without root disturbance. Any good, deep, well drained loam which will suit rhododendrons and azaleas will do, but it may be enriched with some old hot-bed material or decayed vegetable refuse. The plants should be placed 8ins. deep, and if there have been difficulties in previous efforts it is a good plan to set the plants at the bottom of a wide hole or trench, about a foot deep (the subsoil being properly prepared), which is filled up gradually as growth proceeds. A. T. J.

ROYAL CALEDONIAN HORTICULTURAL SOCIETY

MR. ROBERT FIFE presided over the annual general meeting of this Society held in Edinburgh last month. The report of the Council stated that the monthly meetings continue to be well attended. The spring show, which was held in April last, was not the success the Council had hoped for, and it had been decided to discontinue that show in the meantime. As regards the International Show, it was reported that it was most satisfactory from the point of view of the exhibits received. It was found impossible to accommodate all the trade exhibits offered, and quite a number had to be refused, while the space asked for by others had to be much curtailed. Even thus it was, unfortunately, found to be impossible to accommodate all the competitive exhibits inside the hall, and the vegetable classes had to be placed in a marquee outside. Notwithstanding the unfavourable weather, the attendance of the public was satisfactory. It was stated that it is proposed to hold an autumn show in the Waverley Market on September 8th and 9th, 1926.

The following office bearers and councillors were elected, namely: As honorary president, the Right Honourable Lord Elphinstone; as president, in place of Mr. Robert Fife, who retires, Mr. W. J. Thomson (Messrs. William Thomson and Co.); as vice-president, Mr. J. H. Alexander (Messrs. Dicksons and Co.); for the vacancies on the council, Mr. R. L. Scarlett, C.D.A., Mr. William Fife, Mr. R. L. Harrow and Mr. E. P. Laird.

The syllabus of lectures, etc., for 1926 has been issued and the schedule for the show in September is now in the printers' hands.

NEW CARNATIONS

THE following new varieties have been registered with the British Carnation Society:

RAISERS' DESCRIPTIONS.

SYBIL.—Registered by Messrs. Stuart Low and Co., Bush Hill Park, December 8th, 1925. Seedling. Pedigree. Purple-violet. Size 3ins. Spicy fragrance. Habit free blooming. Stem medium.

SUNRISE.—Messrs. W. E. Wallace and Son, Eaton Bray. December 16, 1925. Seedling. Deep salmon. Size 3–3½ins. Good fragrance.

THE FAVOURITE.—Messrs. W. E. Wallace and Son, Eaton Bray. December 16, 1925. Seedling. Flesh pink. Size 3½–4ins. Habit and stem good.

MOONBEAM.—Messrs. W. E. Wallace and Son, Eaton Bray. December 16th, 1925. Seedling. White. Size 3½–4ins. Good fragrance. Very good stem—stiff.

ROYALTY.—Messrs. W. E. Wallace and Son, Eaton Bray. December 16th, 1925. Seedling. Deep mauve marked with cerise. Size 3ins. Habit and stem good; a free grower.

STEPHANIE.—Messrs. W. E. Wallace and Son, Eaton Bray. December 16th, 1925. Seedling. Delicate mauve (peach blossom colour). Size 3–3½ins. Habit and stem very good.

MRS. A. A. VLASTO.—Mr. J. C. Beck, The Nurseries, Henley-on-Thames. January 14th, 1926. Seedling. Rosy purple on white ground. Size 3ins. Fragrance similar to old clove. Habit and stem almost as strong as malmaison. Stems 24–30ins., self-supporting. In habit and constitution unique.

Three Sterling Novelties for 1926

Give them a trial and you will be more than satisfied.

NEW TEN WEEK STOCKS
Edwards' "Super Dreadnought"

This new strain of "Super Dreadnought" Stock grows from 25ins. to 35ins. in height, the giant double spikes measuring up to 18ins. It is branching in habit and early flowering, coming in flower in ten or twelve weeks. I have great pleasure in introducing these "Dreadnought" Stocks to my customers. These will be grown all over Great Britain this season. And I should like you as keen gardeners to try a collection, they are bound to win prizes.

APPLE BLOSSOM.—A lovely shade of blush pink, very fine.
DORIS.—A very lovely ivory white, shaded old rose good habit.
DOROTHY.—A giant lavender, a splendid shade for florists' work.
GOLIATH.—A very fine mauve, extra fine flowers
INDOMITABLE.—Magnificent fiery scarlet, certainly splendid.
LEVIATHAN.—Lilac, massive spikes.
MARS.—Deep crimson, very good.
NEPTUNE.—The darkest Blue Stock, splendid shade.
PICTURE.—A magnificent cream pink that everyone will want.
SNOWDRIFT.—This variety is a champion, being pure white.
SUNLIGHT.—A lovely shade of yellow, very good.
TOPSY.—A most lovely shade of rose pink.
MIXED.—Special hand mixed, being made up of equal proportions of the above-named varieties.

All above, **6d.** per packet.

NEW SECOND EARLY PEA
Edwards' "Fifty-Five"

To all my customers I would recommend a trial of this New Second Early Pea "Fifty-five." It is rather an early second, coming along almost immediately after Sherwood, and as a succession to my Twelve Inch, is very good. "Fifty-five" is only 18ins. in height, and is one of the heaviest cropping Peas I have ever seen, its dark green pods are closely packed with peas of a fine dark green, full Marrowfat flavour, and usually about seven to nine peas in a pod; the pod itself is slightly curved, and it is not exhibition size, but as a *wishy* pea I believe it has a splendid future, the haulm being literally covered with pods. I am sure that a trial will convince all that "Fifty-five" is the heaviest cropping Dwarf Second Early Marrowfat Pea.

Per pint **2/-**

NEW ONION
"Ipswich Champion"

This New Onion is the heaviest type of Exhibition Onion there is on the market, raised by an exhibitor and shown at the largest shows in Great Britain, where it has always taken prizes. The stock of seed is rather limited for this year, and I cannot offer by the ounce. This Onion will grow to 3½lbs. in weight, and all onion exhibitors must give it a trial. Per packet **1/-** and **2/-**

AUTUMN and WINTER BEAUTY
In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

BALSAMS FOR PRESENT SOWING

BALSAMS are not as popular as they used to be, yet they are exceedingly pretty things for greenhouse decoration, easily grown and quick to come into flower. A succession of bloom may be kept up by sowing seed from the present time until May and we would urge beginners to give the plants a trial.

Balsams are of little use for supplying cut flowers, and yet the flowers themselves are of a delightful waxy nature, with great purity and freshness of colour. Though nearly always grown in the greenhouse, they can be used for bedding purposes and from July to September they will give a very pretty show.

Seed is sown thinly and just covered with fine sifted soil; kept in a moist atmosphere round about 55 to 60 degrees, the young seedlings will soon be ready for transplanting and this may be done into boxes or small pots. If pots are used, plunge them in fibre or leaf-mould as this keeps the soil moist and obviates too frequent waterings.

When potted on again after this, add to the compost a dash of cow manure; the plants will develop rapidly in this, especially if the air of the house is moist, for two requirements of the balsam are a humid atmosphere and a porous, well drained compost.

The young plants, like all other seedlings, keep sturdy and strong when near the glass and they should be kept on a shelf, if possible, until placed in their flowering pots. Six-inch pots serve for ordinary specimens, but strong plants may do with pots a size or two larger. Water with care, but yet do not let the soil become too dry; over dryness will surely bring an attack of aphides. Near flowering time apply liquid fertiliser at occasional times, but do not force by placing the plants in too high a temperature.

Seed is listed at ordinary prices, usually to colour—pink, rose, violet, scarlet and white—but the beginner will be safer using mixed seed, for the first time, at least. A dwarf class is also listed; the flowers of such plants are exceptionally large, but they never exceed 9ins. in height, a point which makes them most useful as bedding plants. Let it be noted that plants must not be bedded out before the beginning of June.

As a last point, we again urge strongly the growth of such plants, because they are so seldom seen nowadays as to be uncommon; most readers welcome a change in garden and greenhouse designs, and no better plant for this will be found in a catalogue of half-hardy annuals.—CLYDESDALE.

ALPINES FROM SEED

THE severe frosts which prevailed throughout the greater part of November and December prevented, to a large extent, the work of dividing up rock plants, for undoubtedly the former of these two months is usually a time of great activity in the rock garden.

Having lost the autumn season and being nowise sure of good weather for dividing plant

POTATO CATRIONA

Among the many well known varie including Majestic and Up-to-Date, ra by the late Mr. Archibald Findlay of Aucht muchty, is one which is well worth a tr This is Catriona, an immune variety with distinctive purple patch at the rose end of tubers round the eyes. In season it is abo the same time as Eclipse, and has the same ha of continuing growth should it not be neec as soon as it is first ready for lifting. If w sprouted it will come in nearly as early as Sharp Express, and the quality, especially when lift as soon as ready, is of the finest. It is also excellent cropper, and one of the finest variet for exhibition.

At the same time as he raised this, Mr. Find raised a number of other purple-eyed varieti and, unfortunately, after his death there w some confusion as to exactly which was t true Catriona. Our stocks won most of t leading prizes at the National Potato Sho in 1924, and first prize at York Potato Sho in 1925, among numerous others. We ha supplied this stock to many merchants up a down the country, and those wishing to obta the stock should make enquiries from th local seedsman, and failing being able to obta it from him, we shall be pleased to supply dire

HENRY ECKFORD, Headquarters for Sweet Peas, Dept. 6, Wem, Shropshire

crowns in the spring, it is obvious that the alternative course, increase by seed, is worthy of immediate consideration. Seed harvested last season, providing that it was allowed to ripen and dry off properly, will, if sown now under proper conditions, germinate readily, and, while certain of the seeds—*viz.*, gentians and primulas—were better sown soon after being collected, the majority of the rock plant seeds are best sown now. It is essential that the soil be in a very fine condition. A medium of good loam and leaf soil, kept open and porous by the inter-mixing of sand, will prove the most suitable. If it is intended to sow the seeds in pots, it is important that the pots be thoroughly clean, which remark also applies to the crocks with which each pot should be nearly half filled. Between the crocks and the soil should be a thin layer of leaves or moss, and the soil made fairly firm. The seed should be scattered sparsely and, after being covered with a thin sifting of soil, should be evenly but very gently pressed down with a flat circular piece of wood suited to the size of the pot.

It naturally follows that a fine-rosed can must be used for watering-in and also for subsequent watering.

The seed house will require very little heating, for, since hardy plants are being dealt with, coddling is to be avoided; however, there ought to be some artificial heat to prevent the temperature from falling to anywhere near freezing point. The seed pots should be stood on cinders and covered over with paper until the seedlings are visible. At all times water with great care, and after the third or fourth day make a daily practice of taking off the papers to see if any seedlings are showing. Pots containing the visible seedlings should be taken from beneath the covering of paper and stood on a stage in the same house until such time as the seedlings can be conveniently handled for pricking off. It is advisable to take an occasional look at the hole in the bottom of the pots, for it is there that slugs are to be found. Thin slices of potato laid about here and there may be of some service in attracting the slugs, when they can be readily destroyed. The main factor in raising all seeds, and in particular alpines, is patience, for there are some which are slow in germinating, and, alas! there are sure to be some disappointments.—W. H.

POTTING & BOXING SUMMER BEDDING-OUT PLANTS

EVERY year we see more plants raised from seeds for filling the flower beds during the summer. The majority of these seedlings are raised from seeds sown during January, February and March, and they are available for planting out from May 20th to June 15th approximately. It is very essential to success that all the young plants, and also those raised from cuttings, are very carefully potted and, perhaps, re-potted during the spring months. The aim of the flower gardener should be to possess such specimens that, when the time comes to plant them in the beds, they will be sturdy and soon fill up all vacant spaces between them. One frequently sees plants that do not fill up the beds adequately till early autumn when the time has come for taking cuttings, and then there are few suitable ones, their removal spoiling the general appearance of the beds. Zonal pelargoniums should be potted singly first; then marguerites, followed by heliotrope, the smaller-growing subjects being potted after these are dealt with. The compost, generally, should be a light, gritty one—less so for the pelargoniums than for the other kinds, and lightest for the boxed seedlings. All composts should be in a medium state of moisture when used, and very careful watering will be necessary after the potting has been done.—CHRISTCHURCH.

Launching an offer of Seeds for trial.

Free and Post Free.

We launch this offer with much the same feeling in which we should approach thin ice—gingerly—because the offer might be thought to somewhere hide the cloven hoof.

But as we are neither asking for money nor making any conditions whatever in offering to send seeds free to anyone who cares to ask for them, it is difficult to see where the hoof could be hidden.

In the hope of getting into touch with a larger number of gardeners than we now have the pleasure of serving, we are sending to all applicants, free and post free, one packet each of three remarkably good vegetable seeds:

BEETROOT—BAKERS' SELECTED GLOBE. A beautifully formed round beet with a conspicuously thin tap root. . . . . .

PARSNIP—GOLIATH. The biggest and best Parsnip that has ever come our way. . .

ONION—MONARCH. The largest growing, best flavoured Onion among those that really keep.

All we ask is that only responsible people will send for the seeds and that they will do their best with them when they get them, because it is only on results that we can hope for the distribution to benefit us.

Where results are good we hope that the grower will be encouraged to learn for himself what Bakers' other seeds are like and so bring grist to our mill.

For our part we can assure all such ladies and gentlemen in advance that the behaviour of the three varieties of seeds we are sending may be taken as a trustworthy guide to the growth and production of all the seed we sell.

Bakers

SEED & FLOWER FARM, CODSALL. *Nr. Wolverhampton.*

To anyone who is diffident about sending for the free seeds we shall be glad to send a copy of our complete Seed Catalogue. In many ways it is an unusual list—more informative than most—certainly more comprehensive and with something about it that might be called the "human touch," as distinct from the cut and dried, soulless sort of production most of us are used to.

THE START OF A HORTICULTURAL LIBRARY.

IT is often difficult to know where to start collecting books on horticulture, for their number to-day is legion and is likely to increase as more information is collected and new genera become popular. Still, a gardening library is not only a source of information in the way of reference, but is also a continual pleasure when one has advanced sufficiently to appreciate the literature, technical and otherwise, written around a definite branch of horticulture. A few pounds a year spent on the gardener's bookshelf will never be regretted, provided that the books are chosen carefully, for the worth of the information given as much as the appearance of the book and excellence of the plates.

Up to a year or two ago "Nicholson's Illustrated Garden Dictionary" was the only comprehensive work available to the ordinary gardener, and good though it certainly is, it is now out of date. For those who wish such a book in modern form and in alphabetical order there is Bailey's "Standard Cyclopedia of Horticulture." Up to this year this book has been published at a price perhaps beyond the pockets of many garden enthusiasts, but now Messrs. Macmillan are to be congratulated on issuing it in a three-volume edition at the much reduced price of £4 4s. Although an American publication, it is of great use to the British gardener and will long remain a standard work. The other standard book of general reference is the new edition, published last year, of "The Gardener's Assistant," which specialises in giving detailed cultural information about every branch of garden work, besides lists of suitable garden plants and so on. This is issued by the Gresham Publishing Company at £3 15s. for six handy-sized volumes. Both of these sets are well worth the outlay.

For the more general gardener and those amateurs among whom gardening is now so widespread, a more handy book of reference will be found of greater service, in which they can find a ready answer to all the hundred and one questions which crop up with surprising regularity in connection with one's gardening duties. In his difficulty he will find two volumes of the greatest assistance. The first is "Gardening for Beginners," published by *Country Life*, which will prove of great help to those who are, as yet, just feeling their way. To those with more experience, "My Garden Book," by John Weathers and published by Longmans Green, fills the niche. It has been written for the daily use of all gardeners and is a very useful book.

There are not a few other volumes which can be conveniently classed as works of reference, yet they make their appeal to the specialist rather than to the general gardener. Almost everyone who has a garden grows a few shrubs in it and these are well catered for in our horticultural literature. Undoubtedly the best book of reference on trees and shrubs is that known as "Trees and Shrubs Hardy in the British Isles," by W. J. Bean and published by John Murray. It is a volume which all shrub lovers should possess. For those who only wish to whet their appetite, the recently published little books on shrubs and ornamental trees by the same author, from *Country Life* offices, will give every satisfaction. They both contain much useful information in small bulk.

WOKING STATION, SURREY

AUTUMN and WINTER BEAUTY
In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

Three Sterling Novelties for 1926

Give them a trial and you will be more than satisfied.

NEW TEN WEEK STOCKS

Edwards' "Super Dreadnought"

This new strain of "Super Dreadnought" Stock grows from 25ins. to 35ins. in height, the giant double spikes measuring up to 16ins. It is branching in habit and early flowering, coming in flower in ten or twelve weeks. I have great pleasure in introducing these "Dreadnought" Stocks to my customers. These will be grown all over Great Britain this season. And I should like you as keen gardeners to try a collection, they are bound to win prizes.

APPLE BLOSSOM.—A lovely shade of blush pink, very fine.

CORIS.—A very lovely ivory white, shaded old rose good habit.

DOROTHY.—A giant lavender, a splendid shade for florists' work.

GOLIATH.—A very fine mauve, extra fine flowers

INDOMITABLE.—Magnificent fiery scarlet, certainly splendid.

LEVIATHAN.—Lilac, massive spikes.

MARS.—Deep crimson, very good.

NEPTUNE.—The darkest Blue Stock, splendid shade.

PICTURE.—A magnificent cream pink that everyone will want.

SNOWDRIFT.—This variety is a champion, being pure white.

SUNLIGHT.—A lovely shade of yellow, very good.

TOPSY.—A most lovely shade of rose pink.

MIXED.—Special hand mixed, being made up of equal proportions of the above-named varieties.

All above, 6d. per packet.

NEW SECOND EARLY PEA

Edwards' "Fifty-Five"

To all my customers I would recommend a trial of this New Second Early Pea "Fifty-five." It is rather an early second, coming along almost immediately after Sherwood, and as a succession to my Twelve Inch, is very good. "Fifty-five" is only 18ins. in height, and is one of the heaviest cropping Peas I have ever seen, its dark green pods are closely packed with peas of a fine dark green, full Marrowfat flavour, and usually about seven to nine peas in a pod; the pod itself is slightly curved, and it is not exhibition size, but as a *utility* pea I believe it has a splendid future, the haulm being literally covered with pods. I am sure that a trial will convince all that "Fifty-five" is the heaviest cropping Dwarf Second Early Marrowfat Pea.

Per pint 2/-

NEW ONION

"Ipswich Champion"

This New Onion is the heaviest type of Exhibition Onion there is on the market, raised by an exhibitor and shown at the largest shows in Great Britain, where it has always taken prizes. The stock of seed is rather limited for this year, and I cannot offer by the ounce.

This Onion will grow to 3½lbs. in weight, and all onion exhibitors must give it a trial. Per packet 1/- and 2/-.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.

In the *Field*, a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6.

THE BEAUTY OF MECONOPSIS

SUCH a confirmed believer am I in the importance of the meconopsis in our gardens that I take every opportunity of drawing attention to the fact that it is a lovely flower and that it is not the garden will-o'-the-wisp that many people imagine. In this issue will be found the first of two articles by Mr. Kingdon Ward telling of his latest finds in Tibet, the home of the genus. In these articles will be found not only notes of new species—which, after all, are only of interest to a few at the present moment—but also much interesting information about the conditions under which they grow in their native haunts.

Thanks to the enthusiasm of Professor W. W. Smith and a few Scottish enthusiasts, the meconopsis is slowly increasing in popularity; but if the present rate of increased enthusiasm may be likened to the speed of Stephenson's first train, in a year or two I hope to see it increased to the speed of the Riviera express. I have a feeling, however, that much of the diffidence of gardeners in growing meconopsis is owing to the fact that they look exotic and difficult, and so are a nuisance to grow. I wish I could bludgeon into the heads of all gardeners that, with an exception or two, all meconopsis in cultivation present no difficulties, provided that the would-be grower understands what the plant likes and what it dislikes. Here is a list of a few of their foibles:

M. LATIFOLIA.—Biennial; not wet ground; dry bank or corner of rock garden. Seeds itself.

M. PRAITII and M. RUDIS.—Biennials; fairly moist conditions, but good drainage; border under shrubs excellent. Seed themselves.

M. WALLICHII.—Biennial; ordinary border conditions, but not in full sun; good wild garden semi-woodland plant. Seeds itself.

M. INTEGRIFOLIA and M. SIMPLICIFOLIA.—Perennials; shrub border and fairly moist conditions.

Of course, a number of them are biennial—or at least monocarpic—and many gardeners fight shy of growing biennials owing to the bother of resowing, but I am quite certain that once anyone has grown them they will not give them up in a hurry. The seeds also are easily collected and germinate freely, possibly even better outside than in. There is another thing in their favour: provided the ground round them is not choked with other vegetation, they will seed themselves freely and so save the gardener trouble. Surely no plant could be more accommodating.

So much for information. For those who have not seen them in their glory the best advice I can give is to make a pilgrimage to the rock garden at the Royal Botanic Garden, Edinburgh, during meconopsis time. There colonies, drifts and cohorts of them may be seen, each spangled with their saucer-shaped blooms that stare at one with a most inquisitive persistence. The gem of the collection is undoubtedly Meconopsis grandis, with 5in. saucers, violet or slatey blue with streaks of blue and crimson running through the petals. Like many gems, it has a disadvantage. It is a terribly shy seeder, but it is a perennial. Round the corner you will see a clump of the straw-yellow integrifolia with every blossom nodding in the breeze or, perhaps, the electric blue of Bailey's form of simplicifolia. They have been well named the blue poppy, for large blue flowers of this type other than meconopsis do not exist. Blue is their real colour, and such a blue. With the exception of Wallichii the blues are of the purest—azures and cobalts and electric; while grandis is indescribable, with the shot effects of a butterfly's wing.

Another oddity about meconopsis is that they last well as cut flowers in water; and this is certainly strange, for more fragile and delicate-looking morsels could not be imagined. I saw at Edinburgh a flower of M. grandis of which the stem had been damaged; it had been three weeks already in water when I saw it, and it might have been picked the day before. This is an advantage of which few people will avail themselves, for a meconopsis growing is infinitely better than a meconopsis cut. Still, in years to come when there may be a plethora of the plant—if that is possible—this information may be worth remembering.

Have I said enough to persuade even a few more people to try this incomparable flower? I hope so, for every recruit soon turns into an ardent enthusiast and helps others to learn about the beauties of the blue poppy. E. H. M. C.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

ANNUALS FOR THE ROCK GARDEN, by W. Irvine.
SHRUBS FOR PLANTING BENEATH TREES, by A. Osborn.
THE BLUE POPPIES.—II, by F. Kingdon Ward.
FOLIAGE FOR CUTTING, by R. E. Head.

PLEASE REMEMBER TO TELL OTHERS ABOUT YOUR PLANTS THROUGH THE COLUMNS OF "THE GARDEN."

Digitized by Google

THE POPULAR WITCH HAZELS

DURING the first week in January the brightest outdoor effect at Kew was produced by the Chinese witch hazel, Hamamelis mollis. The majority of the bushes are part of a batch of plants propagated by grafting on H. virginiana a dozen years ago. The best specimens, growing in the box (buxus) collection near the Holly Walk, are 8ft. to 9ft. in height and as much, or more, in diameter.

H. mollis is quite the best of all the witch hazels. It is the earliest to flower has the, largest strap-petalled blossoms, and large, attractive hairy leaves. Massed as at Kew, the delicious primrose fragrance is very pronounced and distinctly pleasant in the wind many yards away from the bushes. When mature, specimens are said to attain upwards of 30ft. in height, but small plants, the first or second year after grafting, or layering, will produce numerous blossoms.

It was first introduced about 1879 by Maries, when collecting in China on behalf of Messrs. James Veitch, but was grown for some twenty years in their Coombe Wood Nursery as a good form of H. japonica. A bush attracted the attention of the late Mr. George Nicholson when visiting the nursery, and its identity was soon established. One very noticeable distinction is that the petals of the blossoms are not wavy or twisted as in H. japonica and H. arborea.

H. japonica, the Japanese witch hazel, is the most commonly cultivated species. It is said to have been first introduced to British gardens about 1862. The typical plant is distinguished by a spreading habit, yellow petals and greenish calyx. As a garden shrub, the tree witch hazel, H. arborea, is readily recognised by its robust, more upright habit, deep yellow petals and reddish brown calyx. Between these two extreme types, however, are many intermediate forms obtained by raising seedlings. The variety Zuccariniana is another distinct plant, tree-like in habit, with pale lemon yellow petals and reddish brown calyx. Dutch nurserymen are sending over as Zuccariniana a form with the typical pale lemon yellow petals but with a greenish calyx, thus having more affinity with the type H. japonica. Our old specimens of H. Zuccariniana with reddish brown calyx resemble in this respect H. arborea.

The variety rubra has the petals more or less stained with claret or reddish brown. A good form is distinct and pleasing, but some of the plants I have seen are evidently seedlings which would be best described as a good yellow-flowered shrub spoilt. It is very evident that all are forms of the one species, H. japonica.

H. virginiana is a native of eastern North America and was first introduced in 1736. It is more interesting than strikingly attractive, opening its yellow blossoms in September before the leaves fall. Old bushes are sometimes seen in shrubbery borders and on old garden walls. The leaves turn a rich yellow in October before they fall, when leaves and flowers give the bushes a distinctive beauty. As a garden shrub it is inferior to the Asiatic species.

HAMAMELIS MOLLIS, BEST OF ALL WITCH HAZELS.

CULTIVATION.

Layering is the most satisfactory method of propagation. Seeds, when available may be sown, but germination is slow and uncertain. Flowering early in the year, pollination is frequently interfered with, though the weather has little effect on the beauty of the petals. Despite the recent frosts, snow and cold biting winds, the flowers quickly recovered from any slight disfigurement and looked as bright as ever. One important point in favour of the hamamelis is that frosts must be very severe to impair their beauty. H. virginiana, flowering in autumn, usually ripens seeds, the seedlings providing good stocks for grafting the Asiatic species, failing any other means of propagation.

The witch hazels are not difficult shrubs to cultivate. They thrive best in a light well drained loamy soil with leaf-mould and peat, if available, added to give the young plants a good start. They do not transplant readily except when young, and hence it is desirable to place the plants in their permanent positions when quite small. The situation should be a sunny one. A. O.

SOME EARLY HARDY FLOWERS

UNFORTUNATELY our climate does not lend itself to show off the beauty of early spring plants, many being deprived of their beauty long before their time by the fluctuations of temperature. How welcome is a clump of the Christmas rose, Helleborus niger, seen in full flower when favoured by a mild winter. By taking the trouble to place handlights over them, flowers may be had of an intense whiteness.

Soldanella alpina is a lovely little gem, with its dark green, rounded leaves, flowers deep purple, bell-shaped and beautifully fringed, borne in threes and fours on stalks a few inches long. In its mountain home it pushes up its heads through the snow, not waiting until the latter is completely melted. This alpine succeeds best when planted in a semi-shady damp position in peaty soil, but also flourishes in well drained borders. For pot culture the plants should be potted in well drained, peaty soil and then plunged on the north side of a hedge, where they never get the full sun. Other species worth growing are S. montana, S. Ganderi, a dainty white hybrid; S. Clusii, a very rare variety of alpina and freer flowering. These all succeed under the same treatment. The snowdrops are such well known favourites that they call for no comment. When planted in broad masses they produce a beautiful effect.

Planted in sheltered nooks at the base of a rockery, Cyclamen Coum and its variety, ibericum, prove quite hardy. The deep red flowers of C. Coum form a

Digitized by Google

welcome addition to the spring display. C. C. ibericum, which is classed as a species in some works, but which is really a geographical form of C. Coum, has larger flowers than the type and a distinct white zone on the leaves; it is the most valuable for decorative purposes. Then the anemones furnish us with some delightful subjects. A. Hepatica and its varieties, with red, white, blue and double forms, should be found in every garden. They do well in almost any position, but are rather partial to lime rubbish, which should be added in moderate quantity. A. angulosa is a finer plant altogether, the flowers being much larger and very freely produced. This plant also retains its foliage through the winter and thus the flowers have a background to set them off. Other well known favourites belonging to this genus are A. apennina, A. a. var. blanda and A. Robinsoniana.

By planting bulbs of the vernal snowflake, Leucojum vernum, and Scilla bifolia together, a very pretty effect is obtained. Both being in flower at the same time they show each other off to advantage. Aubrietias should be used in quantity for early flowers, as they will give good results in almost any position, but they prefer a sunny aspect. They are excellent rock plants and should be lifted in spring after flowering, divided and planted on a shady border. By autumn they will have made good plants and should then be transplanted to their flowering quarters. A. deltoidea has purple flowers and is a very free bloomer. There are several varieties of this species, ranging in colour from purple to rose, the best being A. d. Leichtlini, a comparatively recent introduction, with deep, rosy flowers. It is a distinct break from the ordinary run of purple and violet-purple seen in the older varieties.

Among the early-flowering saxifrages one of the best is S. Burseriana. Given a sheltered position with a southern aspect and exposed to the full sun, its tuft of glaucous foliage will be covered with a mass of large white flowers, which are borne singly on stalks varying from 1in. to 4ins. high. Bits of sandstone should be placed round the plant to keep the roots cool in summer and to permit of good drainage in winter. S. sancta forms a beautiful dark green carpet and when covered with its short, dense spikes of yellow flowers is a picture not soon forgotten. S. oppositifolia and its numerous varieties, ranging from white to ruby-red, are very free rock trailers and are not particular as to the soil, although a half-shaded position in peaty soil suits them best. Most of the saxifrages give their best results under pot culture, with the protection of a cold frame; the flowers produced are then of a better colour and substance than those grown outside. Of course, I am only speaking of the early-flowering saxifrages, which well repay this treatment. S. luteo-purpurea makes a lovely plant when treated in this way with its light yellow foliage. Saxifrages like the latter succeed best when left undisturbed in pots for two or three years, but care should be taken to provide them with good drainage and porous soil. Do not over-water in winter.

THE EARLY-FLOWERING YELLOW DRABA AIZOIDES.

Hyacinthus azureus is an early-flowering hardy plant, well worth a place in any garden, however small. Its pale blue flowers are borne in densely packed racemes about 6ins. high. Other well known favourites of this species are H. amethystinus, perfectly hardy and of the loveliest blue imaginable. H. albus, a pure white form of amethystinus, is also a most delightful variety.

The genus draba is another interesting family and contains several noteworthy species, both on account of their tufted habit and earliness of flowering. Among the earliest and best may be mentioned D. Aizoon, D. bruniæfolia and D. aizoides. These are all yellow flowered species and make neat little pot plants for the alpine house. D. Gigas is a white-flowered species, strong growing, about 6ins. high.

One of the best plants to grow at the foot of a warm wall facing south is Iris stylosa, also called I. unguicularis, a native of Algeria, but long ago established as a garden favourite in this country, where in a sunny, warm, fairly dry position it grows like a weed and flowers in winter and spring with extraordinary freedom. It forms tufts of long, narrow leaves among which the flowers may be found nestling in winter, even in frosty weather. They are as charming in form and colour, a soft purplish blue, as they are deliciously fragrant and a bunch of them in a vase in a room is an object of delight. There is a white variety which has less charm and a broad petalled variety, speciosa, which has more. When growing in early summer the plants enjoy plenty of moisture at the root, but at other times drought has no perils for them, indeed, they are all the better for it. The best time to transplant is April or early September.

The Glory of the Snow, Chionodoxa Luciliæ, should not be forgotten, but ought to be found in greater quantity in gardens than it usually is. Its racemes of blue flowers, with their white centres, make their way early through the ground and I have seen them in full bloom at the end of January. C. gigantea and C. Allenii are larger forms of C. Luciliæ.

Another useful plant for the spring border is the arabis. There are several species worth cultivating, the best known being A. albida fl. pl. The flowers remind one of a double stock and are useful for cutting. Another species worth growing is Lucida variegata, single white flowers and pretty, variegated foliage. These, with Alyssum saxatile, are very good rock trailers, and when hanging over a crevice between the stones are seen at their best.

THE BLUE POPPIES—I

BY F. KINGDON WARD.

EVERYONE knows that the home of the genus meconopsis is in the Himalayan and Sino-Himalayan mountains. Those popular favourites, M. latifolia, M. Prattii, M. Wallichii, M. integrifolia and others all come from that region, as, in fact, do all known species, save two.

In the course of our journey in Tibet in 1924, we collected eleven or twelve species. Of these, three are definitely new; two more may be. Another three, though they present certain distinctive features, I hesitate to raise to the rank of species, and am content, for the present, at least, to call them well marked varieties.

But I am here less concerned with the botanically new than with the garden new, and easily the finest species of which we collected seed was known botanically from an incomplete specimen collected by Major Bailey as far back as 1913. There is an element of romance about this plant, now happily in our midst, for its mangled, or rather fragmentary corpse has lain in the plant mortuary for twelve years, while none outside a few specialists had ever even heard of it, let alone realised what an angel unawares rested there awaiting resurrection. As a matter of fact, the only really familiar species of which we gathered seed were M. horridula and M. simplicifolia var. Baileyi—a plant which must not be confused with M. Baileyi; even M. impedita var. Morsheadii is new to cultivation.

Now to take the plants in order of probable garden merit. M. Baileyi (K. W. 5784).—A tall perennial, the rootstock sending up from a clump of large petiolate leaves, several leafy stems 3ft. high. The flowers are borne on long, simple axillary pedicels, each stem carrying from four to six. They are sky blue, with bright golden stamens, and are slightly nodding, of fair size and scentless. The sea-green of the leaves is a feature. Its closest allies are the little known M. betonicifolia from Yunnan—one of Delavay's plants, and the equally little known white-flowered M. superba from Bhutan. M. Baileyi and M. betonicifolia come very near to one another, in flower and foliage, but the long style of the latter is sufficient to distinguish it. M. Baileyi is, I think, one of the most enchanting blue poppies I have ever seen. It has not the rather perky stiffness common to the prickly blue poppies, such as

THE YELLOW MECONOPSIS PSEUDO-INTEGRIFOLIA.

M. latifolia, beautiful as that is; neither, to be fair, has it the overwhelming mass of flowers seen in M. robusta or M. Wallichii. But it has an air of grace which the former lacks, and it never takes on the ultimate untidy appearance of the latter, when the flowers begin to come undone. There is something wonderfully attractive about M. Baileyi, with its flowers fluttering shyly out from among the sea-green leaves like a troop of blue butterflies.

It is a woodland plant and must be grown in real shade, under trees. All it asks are shade and ample moisture, though it cannot abide bog. Loam is its fancy, loam, deep and cool, without lime; a light soil with a good admixture of sand to secure easy drainage. It flowers in the middle of June.

Seed of M. Baileyi has germinated remarkably well, and the young plants, which might flower in 1926, look robust and healthy. There are hundreds of seedling plants in this country, and their prospects are bright. Coming from the shelter of woods, the conditions under which it will have to live among us will be far more uniform than in the case of a rock plant for example; coming from a moderate elevation, 11,000ft. to 12,000ft., it will not feel the change much, and being perennial it can be relied on to look after itself.

Secondly, M. Florindæ (K. W. 6038).—This is a very different plant, though it has one thing in common with M. Baileyi; it comes from the forest.

M. Florindæ is a dwarf yellow-flowered poppywort, biennial, with a small radish of a root and a slender stem, not above a foot high, bearing a few linear leaves and two or three nodding flowers. It belongs to the series cumminsia, but as none of the species of that series is in cultivation, this will not convey much to the horticulturist, however expert. The fact is, the

THE SHADE-LOVING MECONOPSIS BAILEYI

Digitized by Google

other species are high alpines, from shockingly wet regions, which will not do with us. Seed of one or two species has been sent to England, but we have heard nothing more of it, so conclude that, if it ever germinated, the young plants soon went to their long rest.

But M. Florindæ promises to be an exception. It comes from a moderate elevation, about 12,000ft. or rather less, and it grows in the forest, heavily shaded, on loamy banks, in a soil composed largely of leaf-mould. We should have no difficulty in providing it with everything it requires.

M. Florindæ is a new species, and the only dwarf, yellow-flowered species known. Nor does it appear to be common in Tibet, for we found it in one restricted locality only, though abundant there among the rank undergrowth beneath the trees. It flowers in July-August. These two I believe to be valuable additions to the hardy flower garden. M. Baileyi for the wood, M. Florindæ for shady nooks in the rock garden. Both would be better for massing.

I pass on to two species which are a little more doubtful than the above, being alpines, though not high altitude plants as alpines go in this region.

M. pseudo-integrifolia variety (K. W. 5749) is a plant of the rhododendron moorland, with big yellow moons of flowers. It grows 2ft. to 3ft. high and differs from the type chiefly in technical details, such as the proportionately longer style, the larger number of flower scapes, more pronounced hairiness and so on. It is, perhaps, a finer plant than M. pseudo-integrifolia, and is at first sight so distinct as to deserve a name all to itself; but as it has the characteristic habit of the type, though in an exaggerated form, I have not thought it worth while to make a new species of it. It is biennial and it flowers in June and July; should it prove quite hardy, as is likely, it will be a valuable plant.

SHOWING HOW M. PSEUDO-INTEGRIFOLIA IS A PLANT OF THE RHODODENDRON MOORLAND.

K. W. 6245 is a mysterious plant, not seen in flower, of which we collected fruit and seed. There is the cut of M. simplicifolia about its jib, but it has a longer style, and twice as many flower scapes as true M. simplicifolia.

It was not till late October that we came across this plant in the alpine region; it then drew 2ft. of snow. However, it kept afloat bravely, ripening its seed under very adverse conditions, and we collected it as a matter of principle.

Generally speaking, it is the plants from the bare, hungry screes, such as M. brevistyla and M. speciosa, which will not survive our conditions. We cannot even remotely reproduce the conditions to which they are accustomed. Their roots descend 3ft. into what looks like pure gravel, without a shred of humus in it; but it is perpetually moist beneath, nevertheless. The glare is intense, even on a dull day; rain falls more or less without cessation for three or four months, and then comes drought, a cold, bitter drought, which lasts till snow comes to relieve the intense radiation on the scree. In spring the snow melts, and there is ample water for the young plants, which lasts them through the heat of early summer till the rains break again.

WALL GARDENING

IF, by good luck, your garden rises boldly and you wish to terrace it with tiers of flat herbaceous borders, you can revel in a type of rock gardening that has its own peculiar lure. The choice of scheme is difficult, simply because so many press their claims, but the method, of course, is to choose one scheme and stick to it, allowing free variations within its limits.

Suppose you elect to work with boulders. You have built your firm broad road at the foot of the slope—winding or straight, as you please—after throwing up the soil for the first terrace. You begin now to build the terrace's retaining wall; and to the end of my days I trust the boyish zest in this part of the adventure will never leave me. It is dry-walling, of the sort known to builders of our limestone fences that rove endlessly across the pastures. The old rule of "two on one and one on two" holds good. That is to say, your wall must mount so that each gap of the lower line of stones is bridged by a rock of the line above. In this way you avoid the perpendicular cracks which are lines of weakness, and prophetic of an early fall.

CASCADES OF AUBRIETIA ON A RETAINING WALL.

So much goes to the joy of building. The trim look of the shallow trench made ready for the lowest row of stones—the mingled odours of clean, sharp gravel and the damp garden mould you rake constantly to the level of the wall as it mounts up—the nicety of judgment asked in the choice of each boulder before you set the plump fellow in his place—all are part of the delight. Then, too, one's mind reverts instinctively to dry-wallers one has known—craftsmen who have always been specially dear to me. One remembers this and that chat with them as they worked up-fell, or one overtook them on the

Digitized by Google

road and you both dropped into the pastime of noting the wayside walls as you passed, to see whether they were well wrought or slovenly. The quiet, sagacious voices of these men return, and many a pleasant and racy anecdote that has nothing at all to do with dry walling.

Such memories do not hinder the present work. They help it. As a dance is aided by sprightly music, the rearing of your boulder-wall goes forward to the quiet chant of "two on one and one on two," till it is finished.

Your first thought when you step back to view your handiwork, is the pity of spoiling its half-rough, half orderly line by planting it. That mood yields, however, and as the days go on you grow enthralled with the affair of "tailoring" the wall. The word was used by a whimsical northern gardener, who explained it by saying that a wall of this kind needed right-fitting clothes, just as a well-set-up man did.

The whole secret of design in planting this type of wall, I suggest, is to have the thought of cascades in mind. Your boulder-community must be chosen from such plants as ripple downward with spontaneous grace and freedom, and the choice is wide. Who can overpraise the company of aubrietias? Glancing down the wall's length, one marks a pocket here and a gap there, and fancy sees already the soft descending showers of bloom. A flower somehow that at close quarters suggests maiden shyness and fresh, youthful charm—but in the mass how vital and aglow it is. From tenderest mauve the colours range to deep-hearted blue and glowing purple. We have made a good beginning with our wall.

Double arabis comes next, with its loose-branching carelessness, and neighbour to it we'll have yellow alyssum, that flowers itself almost to death in a haze of gold-dust glory. Then little rills everywhere of the red-pink nettle, if you can trust yourself to keep its lusty growth in hand—and creeping jenny, to carry on the golden hues when the alyssum has done with flowering.

The single arabis must not be forgotten. Given hard enough root quarters between the rocks it loves, its foliage alone is a joy, and few can resist the white, fresh laundered beauty of its flowers, that dread no winds of earliest spring and tempt the first bees to one's garden. One gets into the habit of pinching a leaf between finger and thumb in passing—as with lad's love—for joy of its keen aromatic scent. And it rambles so becomingly, sure of its nurturing rock.

It has a first cousin, the veined arabis, that ought to be tucked into casual pockets. This seems to be little known nowadays, and more's the pity. Its leaves, green and ivory, pranked with gold, are a sheer delight, giving what no other plant can to the wall-garden's rich mosaic. Perhaps its vogue has gone, because if left untended it returns to its cousin's simple green. The only way to keep its mottled, wax-like charm is to take the plants from their crannies, snip off rooted bits that still keep their motley, and replant them, true and hard, so that they grip their foothold beyond chance of losing it. The trouble is small for a joy that lasts the twelvemonth through.

You have such a broad pattern in being by this time that you can afford to let further planting of the wall wait for odd hours of leisure. It is astonishing how the wall itself, from now onward, will whisper its own suggestions for the future. The best time for receptivity of this kind, I have found, is after a day of rough shooting or some kindred sport that puts a man to rights with himself. You are adequately fed and tired, your pipe burns cool and satisfying. To-morrow you will have a quiet morning with the rock gaps still unfilled. When the morrow comes, you find yourself doing just the things suggested to you overnight by a wall that has its own ideas of dress. It was as well, after all, that you left off where you did. You were in danger of concentrating altogether on rippling streams of foliage and bloom—whereas, by their nature, cascades are isolated from each other. So between the aubrietias and the rest you plant stout clumps of bugle-flower, with its deep satisfying blue—primroses of many colours—crimson thrift and many other heartsome things suggested to you by the boulder wall.

When that is done, take a sort of busman's holiday and prepare the wide, flat bed destined for herbaceous plants. Then return to what is of prime importance in wall gardening—namely, how you order the topmost tier of rock. Choose the plumpest boulders at command, and set them in ordered disarrangement from end to end of your stout wall—sentinels pledged to keep the herbaceous folk from straying into the rock country.

There are twenty ways of planting these topmost boulder-crannies. Once, by grace of luck or suggestion again of the wall itself—a human, living thing by now—I happened on a gracious scheme. The proof of all such plans comes with the flowering months, of course. Imagination may have planted, but you must wait in patience to learn whether the result is merely a pretty conceit or true garden pageantry.

That special wall-top astonished me when "it was in its pomp"—a phrase that has peeped out in earlier articles, and will again, no doubt, because there is no other like it. In the front boulder-crannies, as the months passed, snowdrops and winter aconite came together, bright and new-washed from some far-off paths of heaven. The Cashmere primrose, with its proud heads of mauve, followed in close pursuit. All these flowers that bloom almost in the teeth of winter have the same fresh, well groomed air, as of mettled courage that has fought the vanguards of the storm and won through.

Then came the Lent lilies—fairy children blowing golden trumpets to uncertain weather. And by and by, in the rock clefts behind, the sea-pink bloomed freely, as if the sound of distant surf were in its ears. Land-pinks, of the old-fashioned sorts, glowed with colour and clove perfume. Among them, down the far-flung line of the rock wall, bloomed companies of alpine wallflowers, primrose yellow or orange rich as marigolds. And always threading their pride of bloom, the cool, grey limestone, father to them all, kept his great store of water ready for them through the hardest drought.

They say that the rock gardening lure grows into a obsession. I grant it. But there are fine obsessions, healthy to the core. Battle with upland weather, when you go to the high fells with a farmer obsessed by the need to rescue sheep floundered in the drifts—joy when spring strides out to summer and brings the buttercups aglow in golden-sheeted meadows—they are righteous obsessions, whose litany of praise grows clearer with the passing years.

And the days of roaming the high fells, in mixed weather, in search of such game as may happen to your gun? These, shared by a few comrades and a dog or two, are also a thrifty obsession, and from them you return to the lowland garden, and build into it the heartsome plants that have learned the way of wind and weather.

HALLIWELL SUTCLIFFE.

(To be continued.)

SERVICE FOR READERS

Though so many subjects are dealt with in each issue of THE GARDEN, it must constantly happen that readers seek information which is not immediately available. In such circumstances they should make use of our Service Department. Through its medium each reader's own particular enquiry can be dealt with. No matter what the question is, whether advice is sought as to—

RESTOCKING A GARDEN, COLOUR SCHEMES FOR GARDENS, THE BEST PLANTS FOR CERTAIN SITUATIONS, WHERE TO OBTAIN NEW AND RARE PLANTS, INSECT PESTS, NAMING OF PLANTS, AND THE HUNDRED AND ONE OTHER DETAILS RELATING TO THE GARDEN—

there is always information avialable from a staff of expert contributors and consultants; *and there is no charge for this.* It is one of the additional means of Service which THE GARDEN is glad to render to its readers.

Also, there is the further convenience which the Service Department affords of supplying readers with data about anything that is advertised in the pages of the paper. Thus, on receipt of an enquiry, particulars will be sent of, say, half a dozen things about which the reader seeks information. The only stipulation is that a stamped addressed envelope shall be sent with the enquiry.

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C. 2

ANNUALS FOR CUTTING

OF the vast array of annuals whose charms are set forth at length in the seedsmen's catalogues only a comparatively small proportion are suitable for cutting, hence, if they are wanted for this particular purpose, careful selection is called for, especially if garden space is limited.

One of the best hardy annuals for cutting—of course, sweet peas head the list, but it is unnecessary to say anything more about them here—is Lavatera trimestris in its improved forms. L. rosea splendens, L. alba splendens, and the newly introduced Loveliness, which is deeper in colour than rosea. Clarkia elegans in its double variety—the original single type seems to have practically disappeared—is as pretty in the house as in the border; it is to be had in several colours, but the pink shades are preferable to the ruby-purple and crimson, therefore it is best to eschew mixed seed packets. This, however, does not apply to mixed godetia seed, as the whole range of colour in which this dainty flower is to be had is without reproach, although the best varieties of all, perhaps, are Double Rose, Apple-blossom, Lavender Gem and the old favourite, Lady Albemarle. There is also a pretty and uncommon variety with crimson spots on a white ground, Sutton's Ladybird, and the azalea-flowered type, recently introduced, promises well, although only to be had in rose-carmine and crimson at present. Jacobea (Senecio elegans) is free-flowering and excellent for cutting but, it is better in rose and white than in its purple form. Most of the jacobeas grown are double, but Sutton's Bright Rose is single, taller than the type and more branching in habit. Another useful cutting plant, to be had in pink and white, is the giant balsam (Impatiens Roylei), often seen in cottage gardens, but rarely elsewhere; it is, however, rather too coarse in growth for a small garden.

No flower has been more improved during the last few years than the annual larkspur, which is now to be obtained in tall and dwarf varieties and in several colours, of which the blues are preferable to the so-called rosy-scarlets and mauves. The tall larkspurs, which branch freely, are better for cutting than the short, stock-flowered ones that are so admirable for bedding. Centaurea Cyanus, the annual cornflower, is another plant which is more pleasing and effective in its original rich blue, than in the mixed colours in which it is now to be had. It may be noted here that cornflowers do best if sown in the autumn in the open ground and that they object to transplanting. Lupinus Hartwegii is desirable in blue and blue and white and there is also a yellow annual form, L. Menziesii, which is not as well known as it deserves. To the list of blue hardy annuals may be added Nigella Miss Jekyll. Salvia Bluebeard, the rich hued bracts of which are most effective for blending with other flowers, and the delicate little blue woodruff, Asperula azurea, also admirable in combination with deeper lined blossoms of sturdier growth.

There are plenty of yellow annuals to choose from. Coreopsis Drummondii is one of the most striking and C. tinctoria, brown and yellow, is also good, as are the hybrids in yellow and red shades. Then there are the popular annual chrysanthemums, the most useful being C. Morning Star, pale yellow; C. Evening Star, deep yellow; and C. segetum grandiflorum, an improved Corn Marigold with starry golden flowers and pale glaucous green leaves. C. carinatum atrococcineum and C. c. Burridgeanum, are both showy. A combination of all these varieties in a vase or bowl is exceedingly effective.

Calendula officinalis, the old pot-marigold, the petals of which were formerly used for flavouring broth, has a tiresome trick of half-closing when put in water, but this sin may be overlooked in the case of the fine double Orange King for the sake of its glorious colour. Lemon Queen is similar, but paler yellow as its name implies. The small varieties of annual sunflowers are excellent for cutting and some of the medium-sized kinds, such as Munstead Primrose and Barr's intermedius Crimson King, are useful for filling large jars.

THE VIVID ORANGE BLOOMS OF A MODERN CALENDULA. ADMIRABLE FOR INDOOR DECORATION.

The annual scabious or pincushion flower is now grown in colours ranging from white to deep crimson. Both double and single varieties are good. Sweet Sultan is liked by some people mainly because of its scent, which, however, seems oppressive and sickly to others, but it is long-lived in water, and the improved, larger-flowered sort is handsome. The behaviour of poppies of all kinds is annoyingly uncertain in the cut state. They must be always picked before more than a streak of colour is showing in the calyx and put in plenty of water in a cool, shady room until they open. Some people recommend taking a jug of boiling water to the poppy bed and dipping the end of each stalk in it as cut, while others advocate sealing the ends with a match, but both plans entail too much trouble to be generally adopted. There are many beautiful varieties of annual poppies; the fringed ones are very showy, but the well known Shirleys are the prettiest for vases.

All the annuals hitherto mentioned are quite hardy and may be sown in the open, but where there is sufficient greenhouse or cold frame accommodation available it is best, except in the case of the very few, that dislike transplanting, to sow in pans or boxes, prick out when the second pair of leaves has appeared and move to their permanent quarters in April or early in May, as well grown little plants. This method minimises the trouble of thinning and watering and to a certain extent circumvents the wily slug.

Of half-hardy annuals, cosmos and China asters are among the most suitable for cutting and both can be raised in a cold frame. The former, indeed, is very nearly hardy, as self-sown seedlings survived last winter in the writer's exposed garden and bloomed well. The white, pink and rose varieties of cosmos are equally pretty. There is an enormous selection of asters from which to choose, but for cutting there is really nothing to beat the old Aster sinensis, with its large single flowers on long stems, although the thread-petalled singles, such as Southcote Beauty, are newer. There is a recently introduced crimson variety of A. sinensis named Maréchal Joffre, which has little or none of the ugly magenta tinge that disfigures most of the so-called "red" asters, but it is scarcely as attractive as the clear colours of the original type. R. E. HEAD.

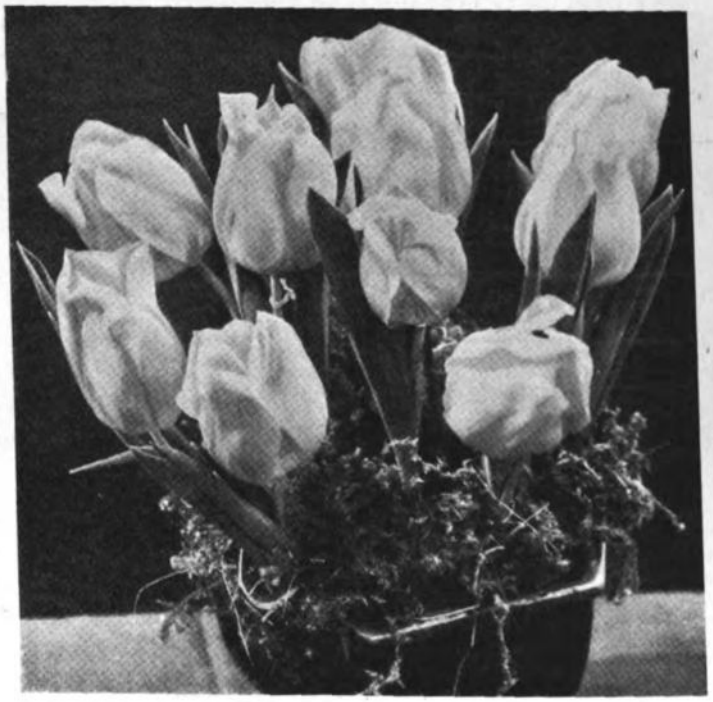
ARE YOUR BULBS GOOD

The successful growing of bulbs o... on a good bulb, a good growing ... and, last but by no means least, ...

st that touch of nake-up, are the or cultivation in They present no the veriest tyro, courage the use house.



A well grown bowl of tulips with flowers on short stems. Some varieties are inclined to be leggy.

Crocus versicolor, an old species.

These illustrations may serve to show all readers what may be accomplished in the more modern trend of growing bulbs for indoor decoration. They may also help to whet the appetites of those who, up to the present, have been doubtful of success and have held their hand from this, the one branch of horticulture which makes the same appeal to the townsman and the dweller in the country.

Digitized by Google

AS GOOD AS THESE?

all kinds in pots or bowls depends
medium, a suitable bowl or pot,
some common sense and patience.

It is only in recent years that the value of the crocus as a pot plant has been recognised.

From time immemorial daffodils have been used in the decoration of the house. With the introduction of such fine varieties as the one illustrated, there is no excuse for the lack of growing a number of bulbs of this favourite flower.

The great advantage which bulbs in pots and bowls have over those that are grown just to be cut is the greatly prolonged life of the flower. In this way they are a distinct economy, apart from the amusement that can always be derived from watching their daily progress during the winter months. After a season in the house they will readily take their place in the confines of the garden.

A fine clump of the winter-flowering Iris tingitana.

FROST DAMAGE in EAST ANGLIA

ANY frost severe enough to damage the common laurel, leaves behind it effects which, however unpleasant they may be, are full of interest. Such a frost visited this east Norfolk garden at the end of November last, continuing with greater or less intensity for three weeks or so. The lowest temperature reached is not actually known; but 24° and 25° of frost were registered in two places on the high ground not far away; and although these readings by amateurs of ordinary garden thermometers cannot be regarded as scientifically accurate, they are probably not far out. It is certain, at any rate, that at the bottom of the valley we have had well over 20° of frost, and I think on one night the temperature must have fallen nearly to zero.

The garden itself, about fifteen miles inland, is situated on a slight southerly slope at the bottom of the river valley. It is cold, damp, and at present wind-swept and unsheltered—disadvantages which are alleviated to some extent by its warm sandy soil. It is newly planted, and the shrubs mentioned below are young, all having been planted within the last four or five years and none having had less than a year in which to establish itself except where stated.

Some of the escapes, no less than the victims, are unexpected. The most surprising, perhaps, is the escape without a trace of damage of such things as Stranvæsia glaucescens and Raphiolepis japonica, which are generally thought to be a little tender; while certain rhododendrons and berberis, believed by us to be hardy, have been badly hit; and even the common laurel has been damaged.

Berberis Hookeri latifolia (Knightii) has been killed almost to the ground. B. Hookeri, under the name Wallichiana, has had many leaves and small shoots killed. The same species from a different source, under the name Jamesonii, is entirely undamaged. This latter specimen differs slightly in appearance from the one that is damaged. It is more compact and bushy, and has slightly smaller leaves. The damaged plant, however, is growing at the lowest part of the garden, slightly shaded, too, by some rather sparse silver poplars; while the other is 50yds. or so farther up the slope, at 4ft. or 5ft. greater elevation, in drier soil and fully exposed. Whether this latter plant owes its escape to its position, or whether it is actually an individual of greater hardiness, does not appear certain. B. sanguinea and a species received under the name of levis, but which appears to be Soulieana, have many leaves killed, but are not otherwise damaged. B. Sargentiana has a leaf here and there slightly scorched, but is practically untouched; while small plants of BB. Julianæ and Bergmanniæ, put in this autumn, have every leaf somewhat disfigured, but none wholly killed. B. Veitchii (bought as acuminata) has a leaf or two browned; but its very near relative, B. Gagnepainii, is absolutely untouched. B. pruinosa is very disfigured, every leaf showing a wide edging of brown dead tissue. This latter condition is found in B. ilicifolia also.

The only member of the Aquifolium group damaged is rotundifolia, which has the edges of a few leaves scorched, while B. japonica, received under the name B. Bealei (hyemalis), has a few leaves killed.

I do not know whether B. Regeliana is evergreen or deciduous, though a plant of it put in this last autumn had the appearance of an evergreen. This little bush when the frost struck it was a most lovely sight. It was thickly clothed in innumerable narrow leaves of a misty purplish green thickly overlaid with a soft dove grey bloom, amid which gleamed here and there flushings of vivid crimson and rosy pink. Long before the thaw came all this loveliness was reduced to ashes, every leaf being killed. The plant, however, is not otherwise harmed.

Young bushes of Rhododendron sperabile and R. æmulorum, about a foot high, and well wooded plants, have had every leaf entirely or nearly entirely killed. R. fulvum, on the other hand, is quite undamaged. This latter species behaved during the frost exactly as it does in drought. It hung its leaves straight down, and rolled them up tightly like lead pencils. A seedling plant in its second year, grown under the number K.W. 4509 and believed to be R. fictolacteum, has its leaves blackened and killed. Farrer's 876 is in almost the same state. Farrer's 878 (plebeium), Kingdon Ward's 4177 and the following of Forrest's: 26, 28, 35, 37, F 14021, F 16291, F 16531, F 16584 and F 20430—some of them very tiny plants—are quite unhurt. Two year old seedlings of RR. ambiguum, arboreum, argenteum, Aucklandii, Augustinii, californicum, catawbiense, ciliatum, ferrugineum, maximum, oleifolium, oreotrephes, polylepis, ponticum, racemosum and yunnanense, partly but not entirely covered by snow, are unhurt; and two year old seedlings of Arctostaphylos pungens have no more than the edges of a few of their terminal leaves scorched.

Lithospermum rosmarinifolium at the foot of a south wall, has had all its green parts killed right back to the hard wood. Convolvulus Cneorum, alongside it, except that the unopened blossom buds and the ends of a few soft shoots are killed, is unharmed. Salvia Greyii, on the same wall, has had its leaves and the softer shoots which are away from the wall killed, but is not really hurt. S. Grahamii is more tender, and I have not yet succeeded in establishing it. Fabiana imbricata is none the worse; but Romneya ciliocalyx at the foot of a south-west wall is cut to the ground.

While, as already stated, Stranvæsia glaucescens and Raphiolepis japonica have suffered no damage whatever, Pyracantha Rogersiana has its leaves badly scorched. Escallonia Donard Seedling, which in the winter of 1923–24 lost all its leaves, is this winter untouched. Clerodendron Fargesii, which in previous winters has had the ends of its soft shoots frosted, is unhurt, and seems now to have acclimatised itself. Ceratostigma Wilmottiæ and C. Griffithii are cut to the ground. Spartium junceum has lost 6ins. or so at the end of every shoot; while a plant sent to me as Notospartium Carmichaeliæ, but which appears to be in fact Carmichaelia australis, has merely its tiny leaves killed, and just a few of the ends of its flattened shoots. It is planted in the south-west angle of a wall and a reed fence.

Of the rock roses, Cistus salviæfolius in the open has had most of its leaves and soft shoots killed. C. florentinus at the foot of a south wall has a few leaves killed.

Of the tree heaths, Erica lusitanica and EE. australis, Veitchiana and arborea alpina are unhurt except that the ends of a few of the softer shoots have their leaves browned. Erica arborea itself was literally shattered to within a few inches of the ground in the 1923–24 winter. The frost seemed not to have hurt either the leaves or the current year's shoots; but all the hard woody branches were burst and splintered as though they had been laid on an anvil and beaten with a hammer. Its remains, which have made little progress since, were protected by snow during this last frost, and so escaped. E. arborea alpina is definitely hardier than the type, as it passed through the 1923-24 winter unscathed.

H. A. GREATOREX.

NOTES OF THE WEEK

SOME MINOR NARCISSI.

SOME of the most charming of miniature bulbs, the tiny narcissi, are but infrequently met with; once seen, their charms compel attention and I would recommend all lovers of interesting and bulbous plants to become acquainted, during the approaching flowering season, with these Lilliputian daffodils.

The golden flowers of N. cyclamineus, with the perianths curiously turned back, not unlike the ears of an angry mule, appear early and are possessed of astonishing lasting qualities; but a few inches high, this little bulb loves moisture, as do the various forms of N. bulbocodium, the hoop-petticoat daffodil. The type, in bright yellow, has given to us some lovely forms, such as the sulphur N. b. citrinus and the more vigorous N. b. conspicuus; there is an exquisite white form from Algeria, N. b. monophylla, but it is a capricious beauty and displays its charms all too grudgingly. All have the queer terete onion-like leaves and distinctive corona.

The small angel's tears, N. triandrus albus, with its drooping, ivory-white flowers, behaves exceedingly well in the rock garden, and like most small daffodils will furnish an interesting and charming pan for the alpine house.

N. minor and N. minimus, forms probably of N. pseudo-narcissus, are dwarf trumpet varieties; "hearty doers," they colonise happily in the rock garden and, in common with their congeners, display their attractions very prettily when "springing" from a dwarf herbage such as many lovely alpines will provide.

Digitized by Google

The richly coloured N. juncifolius, not like a buttercup, must certainly be grown, as must the rather larger, but exquisitely graceful, N. Johnstoni Queen of Spain, also a very durable bulb by the way.

W. P. Milner is a small garden variety which is eminently suited for the rock garden, a fitting companion to Johnstonii.

There are many other forms, such as the interesting N. canaliculatus, but the aforementioned species will suffice to brighten the rock garden and alpine house with the snowalled grace of the "lent lily" during the early months of the year.—RALPH E. ARNOLD.

AN ATTRACTIVE CYDONIA.

WITHOUT a doubt one of the best of the cydonias is C. Maulei, a species which was introduced at a later date than the old Japanese quince. This plant is less vigorous than C. japonica, with more slender branches and somewhat smaller leaves and flowers. The flowers, of a vivid red-orange colour, are very different from those of any other quince. These are produced in great abundance, every young shoot of the plant being crowded with bloom. Even after the spring the attractions of this cydonia are not at an end. Fruits set freely, and these are about the size of small apples and of a golden yellow colour. In the late summer and on to the end of the autumn this quince is almost as pretty as it was when in bloom. As the fruits ripen they develop a spicy fragrance which is very pleasing. C. Maulei is perfectly hardy, and it is a most useful subject for a hedge on account of its spiny character.—S. L. B.

FLOWERING SHRUBS IN PERTHSHIRE.

COTONEASTER SALICIFOLIA VAR. FLOCCOSA.

THIS is an evergreen shrub, about 8ft. high with me. Leaves leathery, wedge-shaped at the base, ½in. to 2½ins. long, tapering to a sharp point; the upper surface is glossy green, the lower one covered with silky white floss, some of which falls away, showing a grey-white surface beneath. Corymbs about 1 in. wide with nine to fifteen flowers. The fruit is round, ¼in. diameter, bright red, usually containing three stones. This species flowers in August with me, and is very free-flowering, and I consider it one of the most showy cotoneasters I have.

SPIRÆA VEITCHII.

A strong-growing shrub 8ft. to 10ft. high, with gracefully arching shoots. Leaves ¾in. to 2ins. long, ½in. to ¾in. wide, oblong, not toothed, smooth on both surfaces, or very slightly downy beneath. Flowers white, small, and crowded in dense corymbs 2ins. to 2½ins. across; calyx and flower stalks covered with fine down. This fine species was discovered by Wilson in 1900 and is a native of central China, and he considers it the best of Chinese spiræas. This species is very free-flowering, producing its flowers on short leafy twigs from the growth of the previous summer, and is quite hardy. Flowers in June, the shoots wreathed from end to end with clusters of white blossoms.—ANDREW HARLEY, *Perthshire*

THE FREE-FLOWERING SPIRÆA VEITCHII.

THALICTRUMS.

A FEW of the meadow rues are well known, especially T. adiantifolium, which produces masses of maidenhair fern-like foliage, that is largely used for cutting purposes. T. aquilegifolium, as its specific name implies has leaves similar to the columbine, and will thrive both in the border and bog garden. A pretty plant is T. tuberosum, with its fern-like foliage and cream-coloured flowers, that appear in June. It delights in a deep, peaty soil and is suitable for the rock garden. Both T. minus and T. alpinum may be planted in similar positions.

The plant I am anxious to see in a flourishing condition is T. Delavayi, a lovely species with pale purple flowers and attaining a height of about 2ft. It blooms in July and August, when it provides excellent furnishing for the rock garden. I have tried it in several positions, such as on a well drained ledge, where the root run was fairly deep, on the level and in a bog, where it was not excessively wet. The compost, too, has been varied and the diet it appeared to enjoy most was a gravelly loam, where the moisture drained away freely, but it was not a real success. After producing spikes 18ins. high the plants dwindled and eventually disappeared. The poet Gray says in his famous "Elegy": "Full many a flower is born to blush unseen, and waste its sweetness on the desert air," and I feel sure in some garden or gardens, T. Delavayi thrives. If so, take the Editor's advice, write to THE GARDEN about it, and thus help others to grow this beautiful plant.

A different tale can be told about T. dipterocarpum and it is one of the most graceful and attractive plants introduced from China by Messrs. Veitch of Chelsea. As a rule it grows from 4ft. to 5ft. high, but in Mr. Allgrove's nursery at Langley it is very robust and the plants exceed the figures mentioned. In fact, I have never seen a better batch although some excellent examples have been noted in Monmouthshire and South Wales. The inflorescence is most attractive and the individual flowers are rose-purple with numerous citron yellow anthers. It is a decided acquisition in the herbaceous borders, extremely useful for cutting and for flower shows during August and September. This plant will thrive in ordinary garden soil, except where it is of a heavy nature and badly drained.

Fertile seeds can be collected in quantity, and this is the best way to increase the stock. Sow the seeds early in the spring in pans of light soil and they will germinate in a cold frame. When large enough, prick off in a border, or pot them singly in receptacles 3ins. in diameter. Two or three dozen plants will not be too many of this delightful meadow rue.—T. W. B.

ONE OF THE MOST SHOWY OF THE COTONEASTERS. C. SALICIFOLIA VAR. FLOCCOSA.

THE DOUBLE LADY SMOCK.

THE double form of the lady's smock or cuckoo pint (Cardamine pratensis) has been a long time in cultivation and has so many good points that one would expect to find it in every garden; yet it is not seen very often.

It forms clumps of dark green leaves, like a neat, finely divided watercress, from which, in spring, it throws up spires of soft lilac flowers that give the effect of a miniature double stock.

The flowers of the wild type soon fade to white, as the Shropshire Lad noticed; but the colour of the double form is deeper and less fugitive, varying no more than to give a pleasant gradation of tone to a patch of plants in full flower.

Its quiet colour is not a common one among spring flowers, and, although it would probably

Digitized by Google

associate well with the palest daffodils or the dead white of the double meadow saxifrage (S. granulata), it makes a complete picture with its own dark green leaves.

It does not seem to set any seed, but, in compensation, it reproduces itself with almost feverish activity by dropping small plantlets from the axils of the leaves on the flowering stem and by sending out roots from the midribs of the basal leaves in autumn; so that no plant can be easier to propagate.

It will grow in any soil, but seems to prefer a damp and rather heavy one; as a last virtue, it does not object to shade.—F. A. H.

PRIMULA SPECTABILIS.

MANY primulas are grown in rock gardens, but few can equal in beauty this charming easily grown primrose.

Primula spectabilis is often planted in a shady place, but it is when fully exposed to the sun, in an open position, that it appears to be most at home and gives more freely of its beautiful rosy blooms.

The clump shown in the illustration has never flowered so lavishly as last spring (1925); apparently the unusually wet weather suited it. This plant is growing in a good rich loam with a very small mixture of peat, but its needs are simple, almost any compost seems to suit it.—J. S. T.

A WELL-FLOWERED CLUMP OF PRIMULA SPECTABILIS IN A SHADY POSITION IN THE ROCK GARDEN.

MELITTIS MELISSOPHYLLUM.

ALTHOUGH a native plant, the bastard balm is not at all common, either in a wild state or in gardens, and there are many inferior subjects cultivated, while its distinctness makes it generally noticeable wherever it is grown. There are two forms in commerce, but in nature the plant varies a good deal, some plants having flowers of inferior colouring. The best in commerce is M. M. grandiflorum. The bastard balm grows a foot or more in height and in summer gives numerous flowers of white with a pink or purple lip. Their hooded form and the contrast, yet harmony, in colour give this plant a distinct feature of beauty. It looks well in the border when in good soil and in a cool position, but it is even better adapted for a cool, partly shaded place near the shrubbery or rock garden. It is a plant though without showiness which has earned the high praise of many competent and highly critical floral writers, and its ease of culture and beauty should commend it to many who do not at present know it. It is increased by division, or, in the case of the ordinary form, also by seeds.—S. ARNOTT.

SOME FUMITORIES.

THOUGH it is not often seen in gardens, Corydalis ophiocarpa is an easy plant with us and a good many self-sown seedlings have appeared, often most unexpectedly, being a long distance from the parent plant. The pale yellow flowers which terminate the tall, slender stems, are not exciting, but the plant fully makes amends for the poverty of these by possessing singularly beautiful foliage. This is what is usually described as fern-like, the large and elegant leaves being very finely cut and, instead of being green or glaucous, as are those of so many fumitories, they are a peculiarly delicate shade of bronzy-blue.

C. cava (bulbosa) alba, which dwells in a shady corner of the woodland, is always a delight, for its glistening pure white flowers in a bold spike appear in February, to be followed by a pretty foliage in a distinct silvery green. The blooms of this plant, moreover, are deliciously fragrant—an uncommon attribute in this genus.

C. capnoides is also an early bloomer with flowers in the predominating yellow of the race, but the very pale blossoms escape mediocrity by having a vivid green spot on the "helmet" of each. C. Wilsonii, a comparatively new species from China, proved very sulky at first, but here, at any rate, it is evidently one of those leisurely plants which, like a season or two in which to settle down. It is now promising a fair show of its extremely delicately-cut green leaves preparatory to putting forth its rich yellow flowers, which also flaunt the bright green spot. But before these have appeared we shall have little C. Alleni, one of the very earliest and prettiest, not often exceeding 3ins. with its perky sprays of pink and creamy-white blossoms.

After all, there is much to be said for that familiar weed, C. lutea, which is naturalised in many parts of the country. For the woodland or wild garden, old walls, neglected corners, the descent to the greenhouse stokehole and such places, there is a plant of the most willing description, of much grace and charm of foliage and one that will take care of itself and flower throughout the season, asking neither admiration nor reward.—N. WALES.

VERONICA SAXATILIS.

ONE may search many, many rock gardens with considerable pretensions to importance without once coming across one of our most delightful rock plants in the person of Veronica saxatilis. If you ask some who know the plant why they do not grow it, some of them will tell you, with a shrug of deprecation, that this rock speedwell "is only a native plant, hence it is not admitted to their gardens!" Yet the excuse is a poor one indeed, and has led to the exclusion of what a trusted critic has told us is the "loveliest of all the alpine veronicas in existence": and can praise reach a greater height than this? Why so charming a little plant should be excluded and scores of poorer exotics cultivated it passes the wit of man to know. And so I desire to utter a plea for V. saxatilis. It is a low, trailing plant with slender, loose branches some 4ins. or 5ins. long only, so that it does not cover a large space. It has glossy, polished-looking, small, deep green leaves and exquisite little flowers of a fine azure blue, with their beauty heightened by their golden anthers and a white eye. It is not difficult to grow in the rock garden in free open soil. In a dry soil I have found it advisable to give frequent waterings with clear water in summer. The rock speedwell may be increased by cutting or seeds—DUMFRIESSHIRE

THE GIANT BELLFLOWER.

AMONG the bellflowers is classed the handsome hardy perennial Ostrowskia magnifica. This uncommon plant can be grown under the same treatment as most of the border bellflowers, except that it must invariably be protected in some way from strong winds and at no time be denied the sun. It revels in a porous medium loam and, feeding grossly, must have a fair share of manure. It reaches to a height of about 5ft., forming a fine spreading bush. The flowers are of the familiar "bell" shape and of great size, some 5ins. to 6ins. across. They are somewhat fugitive, but a good plant produces them in surprising profusion and quick succession, which atones for any failing in that respect. It does well also in a cold greenhouse. Roots may be obtained for planting now or seeds may be sown. A seedling plant flowers the third season.—LANARKSHIRE.

A BEAUTIFUL EVENING PRIMROSE.

A VERY attractive evening primrose, which should be more widely grown, is Œnothera speciosa. This plant, which is a native of north America, produces an abundance of large flowers, which are at first white, but later change to a delicate rose. Unlike the Chilian evening primrose (C. taraxacifolia), which has a low trailing habit, C. speciosa is erect in its growth, with stems that are almost shrubby. The plant forms neat tufts which are usually from 14ins. to 18ins. high and is a true perennial, most useful for borders and the lower and rougher parts of the rock garden. This evening primrose should have a soil that is warm and light, as in heavy cold ground it may suffer serious check during a severe winter. On the whole a thoroughly well drained border of rich loam proves the best and, when the plant is left undisturbed for some time, it forms a tuft of considerable size. This species is readily increased by divisions, cuttings or seed, although for some reason that is not very clear, it does not set seed very freely in this country. A variety of the type, known as C. speciosa rosea, has flowers which are definitely pink from the opening.—S. LEONARD BASTIN.

EARLY SPRING SPRAYING

UNTIL comparatively recent date we were accustomed to speak and write of winter spraying and summer spraying; and, because a considerable proportion of the work that was placed under the former heading belonged to the months of February and March, the impression gained ground that November, December and January were really unimportant months in the spraying calendar. That if our view stands for aught, is an unfortunate misconception, and it is highly desirable that when the object of spraying is to cleanse trees of lichen, algæ or slime and, incidentally, to remove harbourage under which eggs and pupæ of insect enemies may hibernate, such work should be carried out at the beginning rather than the end of winter. It is very essential, even though we may have cleansed fruit trees and ornamental trees and shrubs of mossy growths and slime, to apply sprays which will destroy at birth or awakening a wide range of pests, and the spraying which must be done between the present time and the opening of fruit blossom is of vital importance. In order to differentiate between this and December spraying we adopt the convenient, even if not precisely accurate, term "early spring spraying," there being also for future consideration the late spring programme—covering the period between dropping of blossom and the full development of summer foliage.

February spraying is of great importance, and even the shrubbery and arboretum should be the scene of industrious effort to combat all foes.

Caustic washes may still be used where there is good reason to consider them necessary.

Run no risks with uncertain mixtures. It is not worth while, for when taking the trouble one may as well ensure the maximum advantage, and that is possible when the best brands of caustic washes prepared by firms of high repute are used. There is nothing to fear when an operator knows what he is handling and exercises proper care, the danger lies in carelessness due to ignorance. Do not imagine that even a caustic winter wash is a remedy for all the ills of fruit trees. The soda is specially useful as a bark cleanser, and does a considerable amount of good work when trees are infested with scale and with American blight. Caustic soda, however, is not to be considered as a fungicide, or at any rate should not be expected to displace copper sulphate for the purpose of curing scab, brown rot, canker and other troubles of fungous character. Some sprays are made which contain a certain proportion of copper sulphate as well as caustic soda, and where one has disease in fruit trees and cannot definitely identify its character one of these combined sprays may with prudence be used. The more efficient method, however, is first to cleanse the trees with caustic soda and a few weeks later attack the fungoid diseases with a copper sulphate wash.

One may mix copper sulphate at varying strengths according to the task in hand. For young trees slightly inffected with brown rot or scab about 5lb. of copper sulphate will make a hundred gallons of wash, or a pound to twenty gallons; but in cases where canker is beginning to make wounds and warts on the bark, a spray may be made at double that strength, using 4 oz. of copper sulphate for a 2½ gallon knapsack sprayer. The use of copper sulphate alone must be confined to the dormant period of the trees, later on the only safe method of using copper being to mix it with lime, forming what is known as Bordeaux mixture, a favourite spray for potatoes during active growth. The lime reduces the power of the copper, rendering it safe to use on soft foliage, but while hardwooded trees are dormant there is no advantage in weakening the copper sulphate.

Nobody, I suppose, is really fond of spraying, especially in cold weather, but since we know no more effective or pleasanter means of eradicating the foes of the garden and orchard it is the most sensible plan to make a great effort to accomplish the work thoroughly by systematic procedure — first with caustic wash and then with copper sulphate. For, whereas the half-cleansed tree is not cleansed at all, the thoroughly cleansed tree will in all probability be safe from serious harm for a few years.

A much milder, but extremely useful spray comes into use about this time, or at least prior to the end of February, that is lime-sulphur. True, it is an evil-smelling and rather messy spray, but it has the advantage of being non-poisonous and harmless to the flesh.

Lime-sulphur is so frequently recommended as a fungicide that one is tempted to declare its greater purpose is insufficiently realised by those who presume to teach. Few things destroy aphides as they hatch out from the eggs that have lain snugly in the joints and niches of the small wood as does a good coating of lime-sulphur spray, and it is for this particular purpose it should be used at this season. Later on it may be used as a mild fungicide, but while copper may safely be used on leafless trees, lime-sulphur is of small account apart from its power to slaughter aphides. One moment though, it would be a serious omission to make no reference to the fact that trees covered with lime-sulphur are generally left severely alone by birds, and as the time draws near when finches and sparrows are wont to amuse themselves picking out the buds of fruit trees, gooseberry bushes, etc., it is well to take full advantage of a simple means of checking their onslaughts by spraying with lime-sulphur at the earliest opportunity.

As in other spheres, advances are constantly being made in the production of new and efficient washes, and it will come as good news that a winter wash of non-caustic character has been put to very thorough practical test and has proved to be efficient in the highest degree, while safe and comparatively pleasant to use. This is a tar-oil product of British manufacture, and bears the name of "Mortegg." Another equally efficacious tar-oil winter wash is "Abolene," made by Messrs. Abol, Limited. This is thoroughly reliable for cleaning tree trunks and removing mossy growths and lichens as well as destroying insects' eggs. In addition, it is easy and safe to use. Once these sprays get into more general use, their value and efficiency as winter washes will readily become recognised.

A. J. MACSELF.

CORRESPONDENCE

HARDINESS OF PLANTS

SIR,—I have been much interested in your Correspondence page lately, especially in those letters dealing with the hardiness of plants and our Canadian wild flowers. For instance, Incarvillea Delavayi is said to be hardy in Britain and I. Olgæ tender; now it is quite the opposite here, I. Olgæ having lived in my garden without protection for the past seven or eight years, while I. Delavayi has not yet survived a winter in the garden. The northern form of Ixiolirion montanum is also quite hardy here; while I notice some of your correspondents state that it should be protected.

In my opinion soil and soil moisture have a very great influence on the hardiness of plants. Take, for instance, such western Canadian plants as Anemone patens, Mammillaria vivipara and Opuntia polyacantha. In the wild state these grow on dry clay banks and on rolling prairies in a well drained sandy loam. When planted in good rich garden soil they promptly winter-kill, and can only be cultivated in prepared soil in good drainage. The beautiful Viola pedatifida, which is found in company with Anemone patens, though it does not winter-kill in rich soil goes "blind" in such situations.

Among our native woodland plants few are more showy in their season than Cornus canadensis. In a thin aspen wood a carpet of the white bracts of this cornus makes a brave show, and its bright red berries in autumn render it attractive again at that season.

Linnæa borealis, though not so showy as the cornus, deserves the closer attention of those who care for neat and dainty flowers.

In Lilium philadelphicum we have a very showy flower which seems as much at home in the edge of the woodland as on dry gravelly prairie terraces. It is not at all fastidious as to soil or location, provided lime is present and there is no stagnant moisture near the roots.

One of the most beautiful of our early spring flowers in western Canada is Fritillaria pudica. In Canada east of the Rockies this fritillaria has only been reported from one district in south-west Alberta, where it is known to the school children as yellow bells. With me this fritillaria has taken very kindly to cultivation. The colour is bright clear yellow and, though it flowers very early (from two to three weeks after the snow has gone), still, frost does not injure the beauty of the flower. It is not at all fastidious as to soil, and by the judicious use of heavy and light soils and sunny and shady situations, the flowering season can be prolonged at least two weeks.—F. L. SKINNER, *Manitoba, Canada.*

NEGLECT OF THE FUCHSIA.

SIR,—As a Devon man I must plead guilty to neglecting the fuchsia as a garden plant; but in a county where you can motor through roads lined with wild raspberries, where

Digitized by Google

veronica spreads right down to the sea, and where you can walk down lanes where fuchsias grow wild in the hedges, it is difficult to grow enthusiastic about them as garden plants.

Rather would I say to Devon gardeners: Grow rhododendrons—they flourish amazingly under proper culture, and you can have a blaze of flowers from Christmas Day onward.

As I write, on a January day, Rhododendron Nobleanum is a magnificent sight, R. Christmas Cheer is just bursting its buds, R. præcox and R. Early Gem are unfolding their mauve flowers, while the pure white Chinese almond blossoms show up the crimson and rose colours of the rhododendrons. Camellias also should be grown in the open in Devon.

The reason why we neglect the opportunities of our climate is that all our best gardeners are Scottish and, naturally, grow things they are accustomed to in Scotland.

We are learning, however, and my own garden contains, among others: Carpentaria californica, Eucryphia pinnatifolia Coronilla glauca, Paulownia imperialis, liriodendrons, Cordyline australis, Tricuspidaria lanceolata (the coral pendants of which I admire more than I do fuchsias), Genista fragrans, Punica granitum, Desfontainea spinosa, Clianthus puniceus, Acacia Baileyana, Magnolia grandiflora, M. Soulangeana, M. stellata, Drimys Winteri, Metrosideros robusta, arbutus, Viburnum Carlesii, V. fragrans, Andromeda floribunda, Daphne Cneorum, D. Fioniana, Pittosporum niger, Hamamelis mollis, besides hydrangeas, double-flowering peach, almonds, rhododendrons, camellias, Osmanthus Delavayi, tree peony, Iris stylosa, etc.

There is no credit in growing these things in Devon, and my brother, who lives in London, says we do not know what gardening is. "If you push a stick in the ground in Devon," he says, "it will grow."—S. I. K. *Barnstaple.*

DISTRICT FLOWERS.

SIR,—The Editorial comment on the above in your issue for January 30th strongly appeals to me as a Devonian and I am of your opinion: that every county should be able to claim a few flowering shrubs or trees that can withstand our somewhat variable climate and give a good account of themselves although classed as half-hardy subjects—notably the fuchsia in Devonshire and the many species that thrive in the adjoining county, Cornwall. Some may say that the climatic conditions of these two counties are unique for the well doing of such plants, bearing no relation to that of most other counties, but they have only to refer to the last page of the issue under notice and read of the great variety of such plants that flourish down in Cornwall under twenty degrees of frost some winters. Therein is a long range of suitable subjects to choose from, many of which doubtless would acclimatise themselves after a season or two, providing sheltered nooks and the right kind of soil were given. It is folly to put your trust in the native soil as you find it. To be successful the requirements of the plant must be catered for, whether it is peat, fibrous loam, leaf-soil, sand or lime, each one of which is absolutely necessary, individually, for certain plants. Drainage, too, is important where a clayey soil has to be dealt with: no class of plant such as we are discussing (and few others) can be expected to thrive and give satisfaction in a waterlogged soil, while some may require a slight protection during very severe weather—the cold, cutting winds of early and late spring, some seasons, frequently accounts for the non-success of many a plant, but this ought not to deter a planter from giving a few of the many a trial and chronicling the result.—J. MAYNE.

PLANTS TO AVOID.

SIR,—In connection with the notes under this heading in THE GARDEN for January 30th, I would like to add the name of another plant which has proved a veritable "cuckoo in the nest" in the light soil of our rock garden: this is Arenaria montana. I grew a few plants from seed about three years ago, and the plants have attained such dimensions (in spite of drastic checking each year) that I have had to uproot nearly all. The long roots strike down behind the rocks and creep through the fissures into all sorts of unexpected places, and everything growing near it gets smothered with one summer's growth.

There is no lime in this soil, which is a mixture of leaf-mould and sand, and this may account for it; but I do think it is a plant that, if planted at all, should be grown in a corner by itself where it can hurt nothing else.—K. M., *Rothley.*

PRIMULA LITTONIANA.

SIR,—A lady correspondent gives her experience with Primula Littoniana in THE GARDEN of January 23rd. She was told to keep its feet wet in summer and dry in winter. It flowered well under the wet treatment, but died under the dry. She was then told they were biennials. I first got seed of P. Littoniana, from Glasnevin, in 1918, probably 1917 seed. I sowed it, keeping it very moist, and planted the seedlings on the edge of a small stream of lime-free water. This district is lime-free. They all did well, and I have raised a good many seedlings from them, and two of the original plants were alive and flowered in 1925. Experience has shown me that P. Littoniana likes its feet in the water both summer and winter, although it dies down in the winter. I sow seed in a box or a pot in the autumn or winter, and put the box in a shallow little stream and keep it there until I plant it out. This I do about the second year. I have never had any difficulty with seedlings until this winter, when they were twice lifted out of the earth by frost and were lying on their sides with their roots exposed. I can only say they are still alive.—O'MAHONY, *County Wicklow.*

TOOLS AND THEIR SELECTION

(*Continued from page* 89).

THE same care should be shown in buying the small hand tools which are frequently required for bedding and rockery work, etc. They should be made of good solid steel, which will not bend and crumple up under the slightest pressure.

For those who have to cultivate fair-sized gardens, one of the most useful and labour-saving of all implements is that known as "The Planet Jr." Cultivator. This is an innovation which hails from America, but which is now firmly established on the British market. It is made in many sizes and types, but the smaller hand machines will be of most service to the average gardener. By means of detachable tools and fittings the apparatus can be used in turn for ploughing, seeding, hoeing, earthing up, etc., and where time-saving is an essential its use can be thoroughly recommended.

Quite apart from the tools used mainly for working the soil we have also to consider those which, for want of a better term, we will describe as "keen-edged" tools. These can be divided into two classes, those whose use is confined to lawns, edgings, paths, etc., and those used for the pruning, grafting, trimming, etc., of all garden trees and shrubs. It would not be possible to deal with the former in such an article as this, while the latter class embraces so many separate units that only the briefest glossary can be given. Here, again, it will be found that price is usually the factor which will govern the quality of the purchase, and the importance of quality in fine-edged steel tools will immediately commend itself to all intelligent people. There has of recent years been a great influx into this country of garden knives, secateurs, shears and axes of very doubtful foreign manufacture. Many of them look very fine under the glare of electric light, but very few will bear examination in broad daylight, and it is to be feared that still fewer would stand the test of hard work. To use a budding or pruning knife which is weak in either blade or handle is not only likely to break and spoil a perfectly good tree, but is also distinctly dangerous to the user. Examine carefully the rivet which forms the axle on which the blade opens and see that it is strong and firm, avoiding all specimens which have the slightest sign of "rickets." The question of secateurs has in the past been the subject of much discussion, with the result that there are now many and various types to be obtained, each of which claims to have some improvement over all others. The particular choice of pattern is perhaps best governed by individual opinion; but, personally, I dislike those complicated specimens which seem to consist mainly of patent springs and contrivances, most of which usually form a trap for the fingers of the unwary. Without attempting to launch into scientific detail as to the best shape, cutting angles, etc., of the blades, I would say that the most important point in selection is to make sure that the joint upon which the blades operate is perfectly true and smooth in working, while the blades themselves should be very finely set and work in perfect alignment with one another. The latter point is particularly important if clean and fine cuts are required. In a lesser sense, perhaps, the same remarks will apply to the selection of suitable shears for clipping and trimming hedgerows and bushes. There are, of course, many other tools in general use which cannot be dealt with individually in this article, but the broad principles of careful examination and the avoidance of the "penny wise and pound foolish" practice will be found to cover the satisfactory purchase of them all. Having procured really good tools, the main thing in their after use is to keep them both clean and sharp if the best and longest service is required of them. Wipe any metal tool over with a greasy rag before putting it away and the trouble caused by rust will be practically eliminated.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS

BULBS AFTER FLOWERING.

IT is a great mistake to throw away bulbs which have been used for early flowering. The common idea that these are worthless is quite wrong, providing they are properly treated. Of course, the blossoms in the following season will, in most cases, be inferior, and such bulbs cannot be recommended for pot culture again. In an odd corner of the garden they may be used to form a bed from which a useful supply of cut flowers can be secured at the usual time. As soon as the bulbs are no longer of any use for decoration, cut away the flower stalks, taking care not to damage the leaves. Then lift them out of the soil or fibre, avoiding root injury as much as possible, and plant them *at once* in a bed where they can be left without any further disturbance. Later on the planting of small growing annuals in the same bed does not seem to hurt the bulbs. The writer has found that hyacinths yield especially good results when treated in this way. The flower spikes in the following spring were small, but extremely graceful, and these proved most useful as cut blooms.—S. LEONARD BASTIN.

SAXIFRAGA APICULATA.

THIS is a characteristic member of the kabschia section with its stiff, dull green foliage and numerous 3in. spikes of primrose yellow flowers. It seems to enjoy most a sunny position in pockets which have been well drained and made up with a good compost containing plenty of coarse grit. As it flowers early it is not always a good seed-setter, and as raising from seed may prove a wearisome task, I would advocate that in the first place plants be obtained from a nurseryman.

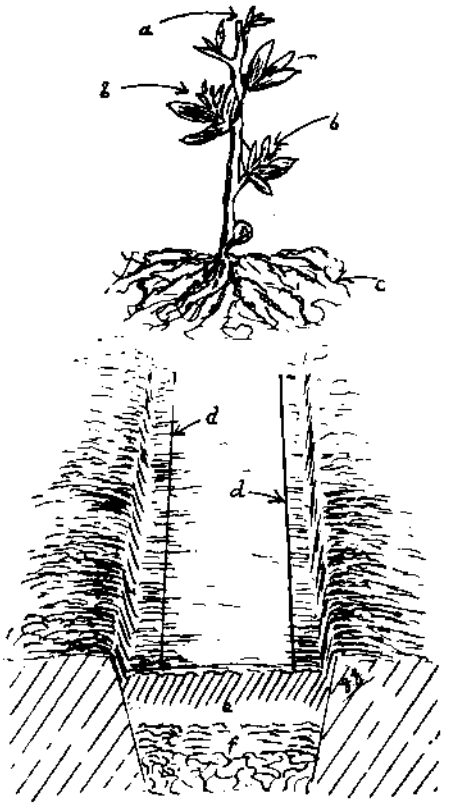
Once established, these plants will form a dense evergreen carpet. Should brown patches arise in the mat, it is advisable to clear out the whole of the affected part and at the same time endeavour to find out the cause of the die-back. Usually it may be attributed to one of two causes, namely, that it has suffered from drought or that there is sour soil in the pocket. In my experience I have more often found the former the cause of the trouble. Having removed the dead portion, take out the soil from the cleared space and work in new soil. Then put in a new plant or, if there is not one at hand, carefully lift a piece from the outside of the mat to fill up the gap. Deep, firm planting in the first instance ensures the best results.—W. HOWELL.

MONTBRETIAS.

THESE charming flowers should be seen in every garden; they are not difficult to grow. I have seen them in dry borders, in poor soil, almost buried under rank grasses, and in borders swamped with water. But in each case the plants existed and bore a few flowers. It is quite a different matter applying real cultivation to them, as the plants respond well to it. The best time for lifting and replanting is after the leaves have matured; these should never be forcibly removed from the bulbs. The latter may be planted any time from their ripening to the month of March. It is not wise to lift and plant growing bulbs. Although they will live and flower in due course, a very serious check is given to the progress of the growth. These plants look very charming in clumps in herbaceous borders, also in clumps near the front of newly planted shrubbery beds. But for yielding cut flowers they should be grown in rows in a specially prepared plot of ground. Few bulbs produce more roots while in growth than those of the montbretia, so it is essential to success that all the bulbs be graded and planted accordingly, the largest 4ins. to 6ins. apart and the smaller ones 3ins. Some well rotted manure should be mixed with the soil just below the point where the bulbs will be placed. Unless the soil is very clayey, it is not necessary to place sand under and on the bulbs. The varied colours are charming.—G. G.

SWEET PEAS INDOORS AND IN THE OPEN AIR.

SWEET PEAS are welcomed and highly appreciated wherever they are grown. Many cultivators sow seeds in October—even late in September—and keep the plants



just safe from frost throughout the winter to supply early blooms both under glass and in the open air. Last year but one, which was rainy and dull, my sweet peas finished flowering outside in October. As the plants were raised from seeds sown in the previous October the plants were growing a whole year. I began cutting blooms, from plants retained under glass, at the end of April, and was able to continue gathering, as stated above, till October—a long season. Well, amateur cultivators may do so, too, if they possess a greenhouse. The plants may be flowered in large pots or in borders. Mine are grown in both. At the present time the young plants look healthy, sturdy and very green. Those that are to be planted out in glasshouses should be so dealt with at once, as the roots will soon become entangled together. If big pots are used, place the richest compost in the bottom; and if borders, bury the manure, thoroughly mixing it with the soil, several inches below the roots of the plants. Plants intended for outside borders should be potted separately forthwith or it will be almost impossible to disentangle the roots later on. If plants are to be stopped, pinch off the point as shown at *a*; strong basal shoots will then grow at *b*, *b*. Roots denuded of soil, *c*; lines in trench shown at *d*, *d*, for the plants to be arranged so, alternately, to form a double row. At *e*, the prepared soil is shown; at *f*, the heavily manured portion with the immediate portion of soil below well forked up but left there. Seeds should also be sown now. —HANTS.

ROSES NAILED TO WALLS.

I SEE so many roses nailed to walls, looking anything but happy, that I have no hesitation in saying that better results are achieved when they are tied to a trellis away from such structures. Certainly, in the summer, when some walls reflect the heat to such an extent as to scorch the leaves and force into bloom immature buds, they do not tend to the well-being of the trees. My own experience prompts me to say that air space between the wall is most beneficial. There are many creepers which take kindly to a wall, but in the case of roses, I venture to say that a trellis, if only a few inches away from the wall, is the best. Especially is this so in southern aspects, where so much planting is done.—W. LINDERS LEA.

GREENHOUSE

THE DIANTHUS (CHINESE PINK).

SEEDLINGS raised in a greenhouse or heated pit about the third week in February will begin to bear flowers soon after midsummer and continue to do so till November. I have grown many batches of plants from seeds so raised for the sole purpose of producing flowers for cutting. The best strains yield 95 per cent. of plants and about 80 per cent. of double flowers. Mix together good mellow loam and well rotted leaf-soil in equal proportions and a free sprinkling of old mortar rubble. Place the compost in clean pans or boxes, thoroughly drained, make the surface level, apply water. Several hours afterwards drop the seeds thinly, about 1in. apart, and evenly on the surface, cover with fine soil a little deeper than one-eighth of an inch, but do not water. Place a sheet of glass on the pan and some paper. If water is needed again before the seedlings appear, immerse the pan gently to its rim in water for a few seconds; the water will soon moisten the whole. Transplant the seedlings in boxes or in a prepared bed in a cold frame when the second rough leaf appears. Almost any border in the garden, if it is not too much shaded, will answer the requirements of the plants. Dig the soil deeply and mix with it leaf-soil and rotted manure. Spread a thin layer of old mortar rubble on the surface to be worked in when the plants are put out 1ft. apart at the end of May.—CHRISTCHURCH.

EARLY CUCUMBERS.

MANY owners of greenhouses and heated pits like to have cucumbers as early as possible in the year. The early cucumbers are highly appreciated, but it is very unwise to make an attempt to grow them unless there is plenty of artificial heat available;

Digitized by Google

then several crops may be obtained from the same structure in one year.

Question.—When should the seeds be sown for the first crop and what amount of heat is necessary?

Answer.—The first week in February is a suitable time for seed sowing; if express cultivation is to be followed, a month earlier would do, but for ordinary culture very early in February, because it should not be difficult to maintain the necessary heat day and night. The day temperature should be approximately 70° and the night one 57°. These are minimum temperatures. If the heat rises a little, good, not harm, will result; if it drops much lower, the growth will be arrested and the leaves will turn yellow.

Question.—Which compost is best for the seedlings and for the plants while they are fruiting?

Answer.—The same kind of compost will be suitable, only that for the young plants should be a little lighter. Good fibrous loam two-thirds, half-rotted leaf-soil one-third. When the plants are ready for planting out, add 1 bushel of rotted manure to 4 bushels of the compost.

Question.—Do cucumbers like plenty of water?

Answer.—Yes, while the plants are growing and bearing fruits, also liquid manure.

VEGETABLES

AN UNCOMMON SALAD.

THERE are many salads that are not generally grown in this country, but which are well worth cultivating if only a small portion of the kitchen garden be allotted to their culture. Cardoon (Cynara cardunculus) is perhaps one of the best salads under this class when well grown, and makes a fine dish when properly cooked. Although it can be grown by sowing seed in the open in April, it is by far the better plan to start germination by sowing the seed under glass as the seeds come up quicker. It will grow in almost any rich garden soil. The seed should be sown thinly on the surface and lightly covered with soil. Over the pots or seed pans sheets of glass should be placed; these must be turned every morning. When the seedlings are well above the surface, remove the glasses. As soon as the seedlings are large enough to handle, pot them up into 3in. pots in a compost of good maiden loam and a little sand. In the early part of June remove the plants into a trench previously prepared. The trench should be about 1ft. deep and the plants should be spaced about 4ft. apart from plant to plant. Early carrots, lettuce or radish will grow well between the plants. Cardoons require to be blanched as soon as they are fully grown, which is as a rule early in the autumn. Blanching should be done carefully, as the stalks, being somewhat brittle, are easily injured. First gather the stems together and tie with some soft string, then place straw bands round to a thickness of 2ins. or 3ins. so that all light is excluded. The band should be left on for three or four weeks. The plants should be cut just below the surface of the soil, the withered leaves removed and the roots trimmed.—GEO. BARTON.

PLANTING POTATOES.

WITHIN the next week or two the planting of first early potatoes should be pushed forward whenever the ground is in a good workable condition. A sheltered south border is the one best suited to grow first early varieties of potatoes. The work of preparing the soil will take less time where the ground has been thoroughly trenched and manured some weeks in advance of the planting period. However, where the soil has not been turned over, it is sometimes advisable to arrange the work so that the ground or section thereof is dug and planted in the one day.

On the border, drills—running north and south—should be taken out with the spade at 24ins. apart and 6ins. deep; into these drills place the sets 9ins. distant from each other; then replace the soil. Along the top of each filled-in drill a low ridge should be formed by drawing the soil up on either side. This ridge will indicate where each line of tubers has been set, but, what is more important, it adds extra protective material to the already partly developed haulms, which, as every cultivator knows, are so easily damaged by frost.

Epicure is the variety from which we usually obtain our first supply of young potatoes. It is certainly not classed among the immune kinds, yet it has been many years in cultivation and, so far, I have never seen or even heard of this variety being affected by the dreaded wart disease. But anyone wishing to plant this variety in "infested areas" should first make application to the Board of Agriculture for a permit.—D. A.

TOMATOES: WHY NOT YELLOW ALSO?

PRESENTLY growers of tomatoes for private consumption will be turning their attention to sowing the first seeds in the greenhouse, and if one could take a census of the operation, it would be found, with very few exceptions, that only red varieties would be selected. Can anyone say why this should be, and why there appears to be a dislike to grow the yellows, which, after all, are very nice, particularly in the salad bowl? It is seldom that one sees them in the markets now, and the usual reply given to an enquiry is, "There is no call for them." The list of varieties of yellows is small compared with red. Is not the cause of their non-popularity due in a large measure to prejudice?—W. F.

CELERIAC.

YEAR after year passes without the English gardener realising that in leaving celeriac out of his seed list he is banishing one of the most useful and delicious vegetables from the household menu. This vegetable can be eaten raw or as a *hors d'œuvre* as in restaurants and in France, boiled whole, sliced in a salad like beetroot, served braised or boiled as celery or seakale, and for soups and stews it is invaluable. Having grown this root myself I am speaking from experience in growing and cooking it. Celeriac is a variety of the ordinary celery and differs only in having a swollen bulb at the base of the leaves. To grow fine plants a long season is required, therefore the seeds should be sown in heat (about 65 degrees) early in March and as soon as the seedlings are fit to handle, they should be pricked out into shallow boxes of good, light soil, 2ins. apart and kept in heat until well established. They should then be moved to a cold frame and hardened off, and early in May planted out in a snug border of rich soil and kept well watered. In June plant them out finally on a level piece of light, rich sandy soil, 18ins. apart each way, taking care to remove laterals that may divide the stem and being careful not to bury the young knob of the plant below the surface. During the following weeks hoe and water well and remove all suckers that appear from time to time at the sides of the plants; gradually remove soil from the sides of the knob, as the more they stand out of the ground the better; but they must never be allowed to cease growing from lack of water or they will not develop well. By the end of September they should have attained a good size. They will be ready to lift about the second or third week in October or if the season is mild they may be allowed to grow on until the first frosts appear, when they should be lifted and stored in sand. First cut all the leaves, except the centre ones. If these are removed the plant will waste its energy in replacing them. If some of the crop is left in the ground, it must be earthed over to protect from frost. I might add that many of my roots were left in the ground and not earthed up this winter and though there has been 14 degrees of frost, they are still flourishing and quite sound.—EVELYN VENNING.

MISCELLANEOUS

THE CULTIVATION OF ORNAMENTAL GRASSES.

THESE are most useful in a cut state during the winter-time, but they are really ornamental, too, while growing in the borders during the summer months if the positions are well selected and the plants are grown in clumps. Good positions are those near the front of herbaceous borders and in like positions in shrubberies, especially in newly planted shrubberies. Where the soil is of a light character seeds may be sown in the open borders about the middle of May, but where heavy, retentive soils obtain, it is much better to raise the young plants under glass—in a frame or greenhouse—and transplant the resultant seedlings in the open border at the end of May. A good general compost is made of old loam, sifted, two parts; leaf-soil, one part; sand, wood-ashes and old mortar rubble, one part. I fill a number of 3in. pots with the mixture, crocks are not required, and place them in a shaded part of a greenhouse; the soil is watered, the seeds sown thinly and very lightly covered with fine soil. If the pots are shaded from sunshine the young grasses soon appear. Then they are gradually exposed to full light and air, grown on slowly and sturdily so that each grass maintains an erect position. In the meantime the ground is manured a little, levelled and prepared for the young plants. It is quite easy to turn out the ball of soil and divide the young plants and their roots for replanting in the border as desired. The seeds may be sown in boxes, but I prefer small pots.

PLANTS TO RAISE ON HOT-BEDS NOW.

THE early hot-bed can be used throughout the summer months after it has done duty in the spring. It is a most useful asset in any garden where plants are required for the flower garden, the greenhouse, porch, dwelling-room window, and vegetable plot. The hot-bed takes the place of hot-water pipes, and the frame on it replaces the box generally used to raise seedlings in the greenhouse. Tree leaves, gathered up last autumn, should be mixed with strawy litter. The heat resulting will be more lasting than that from litter and horse manure alone; it will be steadier and milder. Those persons who prefer to use such beds for vegetables and salads may plant a few early potatoes in a layer of soil 1ft. deep. On the surface sow, thinly, early French breakfast radishes, lettuce (cos and cabbage), and lightly cover them. The radishes will be available for use first, the potatoes last. In June plant cucumbers or marrows. The lover of greenhouse plants will be able to raise young specimens from cuttings of various kinds, to start tubers and to sow seeds of coleus, petunias, cyclamen and primulas. In the bed, old plants, cut back, will quickly begin new growth if the pots are plunged. For the flower garden hosts of seedlings may be quickly raised and then gradually hardened in a cold frame.—GEO. GARNER.

Puzzled

HOW often does it happen that you—who have dealt unaided for years with the hundred and one problems which arise in the garden, are suddenly confronted with some point on which you would like expert opinion?

When such an occasion arises, write to us.

Anyone who needs information on matters relating to Horticultural Pests—and will put his question by letter, will receive from the Director of our Technical Bureau the best information available on the subject quite free of charge.

Keep this offer in mind—don't hesitate to take advantage of it; the knowledge and experience in such matters, accumulated over two generations is gladly at your disposal.

When in doubt—write:—

Cooper, McDougall & Robertson, Ltd.,
BERKHAMSTED,
Herts.

A NOVEL METHOD IN BOWLING GREEN CONSTRUCTION

IN 1924 a most interesting and novel experiment in bowling green construction was carried out at the sports ground of Messrs. Sutton and Sons, Reading, which should gladden the hearts of all devotees to the ancient and honourable game of bowls. One knows that, next to the game itself, the green takes pride of place, and the keen player is generally extremely proud of the green whereon he throws the "woods."

At the same time, the high cost of production of a bowling green generally acts as a deterrent to local authorities and municipalities who are these days launching out into big schemes in providing parks, tennis courts and bowling greens for the ratepayers and it is chiefly of these that I ask close attention. For ordinary bowling green construction the turf must be of the best quality procurable, and that is Cumberland turf. It is most expensive and the transport charges also add considerably to its cost. Then, again, much time, labour and expense are involved in the laying of the turf and altogether it is a costly business.

The following method of construction, which I am about to describe, gives adequate proof that such expense as the procuring and transporting of Cumberland turf is quite unnecessary and, moreover, that a bowling green can be made in a short time without a turf being laid, strange though it may seem. The accompanying photographs will probably convey to the reader a better impression of the experiment than I can hope to give in words.

On January 11th, 1924, the site of the proposed green was selected, but nothing was done till June 24th, when the work of cleaning off a mass of weeds and tangled growth was tackled. By July 1st the weeds, along with the surface layer of soil, had been carried off and the site had now been roughly levelled. It may be added here that the constructional work in connection with the scheme was carried out by Mr. Maxwell Hart of Glasgow. Drains were then laid and the bed given the necessary coat of creosote to ensure against worm attack. A 6in. layer of breeze was then put on on July 21st. The surface soil, which had been previously taken off, was sifted and sterilised by means of a sterilising plant, which was placed towards one side of the future green. Herein lies one secret of the success which has attended the experiment. I might just call attention here to one important point which should be borne in mind by those who contemplate seeding bowling greens, and that is that if it is necessary to sift the soil to remove stones, etc., this can only be successfully accomplished during dry weather. Therefore, this portion of the work can only be carried out during summer, for the soil is rarely sufficiently dry at other seasons, unless it is possible to store it under cover. By means of this process of steaming, all weeds, weed seeds and soil pests were killed, *i.e.*, the soil was rendered absolutely pure. In order to let the reader really understand the great value of sterilisation, one of the photographs shows a large heap of the top soil used, showing the immense number of strong and healthy germinating weed seeds which it contained before undergoing the process. The soil, when sterilised, was then applied on August 1st, on top of the breeze. On September 1st, a few days prior to the sowing of grass seed, a light dressing of complete grass fertiliser was given to ensure vigorous and uniform growth. Then, on September 4th, 2 cwt. of a special mixture of seed, composed exclusively of the fine-growing varieties found in Cumberland turf, was sown, and the result was clearly apparent on October 2nd, when a fine, thick, weedless turf clothed the site less than a month from the date of sowing. Growth was so rapid that the first cutting with the scythe took place a fortnight later and in another three days the mower was used for the first time, the knives being set high.

Now that the details of construction have been noticed, it might be interesting to compare the cost of this method with that of turfing. The cost of making a proper foundation is the same in both cases and therefore can be eliminated. It is estimated that the cost of obtaining Cumberland turf, including transport charges and those of laying, would have run to a few hundred pounds, while the expenditure involved by Messrs. Sutton was roughly, for soil sterilisation, £100, plus about £25 on grass seed. The method is thus far and away a cheaper one and at the same time has given as good results. This was proved by the fact

BEFORE AND AFTER.

A HEAP OF SOIL BEFORE STERILISATION.
Note the mass of weeds.

Digitized by Google

that in August last an English Bowling Association team attended for the formal opening, and the members were surprised and delighted with the playing qualities of the turf. After the conclusion of the game Mr. E. E. Moore, vice-president, stated that his association had opened many new Cumberland turf greens during the year, and the playing of these had been much rougher and heavier than the green they had just played on.

When it is recalled that the whole operation was carried through in a period of some fifteen weeks, it will be recognised that this system has much to recommend it and holds out great possibilities for the future, more especially since the demands of bowlers are becoming more exacting every season. G. C. T.

BOOK REVIEW.

AMONG the many flowers which have captivated the hearts of all who garden in these islands there stands one whose rise to the forefront of the horticultural world has been almost phenomenal. It has been called the Queen of Annuals—which it is—but it is probably better known by its own name of the sweet pea. I was reminded of its beauties the other day on reading through a small book, "Sweet Peas, Their History, Development and Culture," by C. W. J. Unwin (Heffer and Sons, Cambridge, 5s. net), which came into the office. As books go nowadays it is not large: rather is it of that convenient size which can be slipped into one's pocket. It is a very readable book, wherein hard and bare facts are treated in a simple and lucid style which will be readily followed by all. Such details in culture as the sowing of seed, transplanting, training, and the other hundred and one little items, do not lend themselves to what might be called picturesque writing; but Mr. Unwin combines interest with his instruction and so whets one's appetite for the next chapter.

As its title implies, the book covers a wide field, and everything which the enthusiastic grower of sweet peas requires will be found within its pages. An exceedingly interesting account of the history and the origin of our present-day sweet peas is given in the first chapter, in which the names of many pioneers in the horticultural world are passed over in review. Its development has been rapid in this country and, of recent years, in America and Canada, and the author predicts a still wider field embracing our other colonies and other parts of Europe. Several of the facts and figures which the author quotes give one furiously to think of the importance of this flower in horticulture.

The subject of the raising of new varieties always forms an engrossing study even to the uninitiated, and the reader will find many of his unspoken questions answered by the author in Chapter II, where this subject is dealt with at some length.

It is rather interesting to find in this little book a short review of Mendelism. Such undoubtedly leads to a better understanding and appreciation of all that crossing involves, and gives us some indication as to where continued hybridisation is likely to lead us. From there the author treats of the three distinct classes of sweet peas now met with—the late-flowering type, the Cupid type and the early or winter-flowering kinds. Then comes the practical part of the book, that devoted to culture, which will be found a perfect mine of information. Every operation in connection with the growing of sweet peas is clearly and simply explained. Some forty pages are devoted to "growing for exhibition," embracing all those points which make for success. Useful hints are given on how to exhibit, while a list of modern exhibition varieties completes the chapter. Many may not agree with the list which Mr. Unwin puts forward, but any selection must be considered arbitrary, and the inexperienced grower who takes up exhibition work will not go far wrong if he selects the varieties given. To allay the fears of those who may be under the impression that the growing of sweet peas may be beyond their powers after they have digested the chapter on the exhibition system, the author gives a few hints on their more general culture and also on greenhouse culture. Much helpful information is to be gained from reading the few pages on diseases; while the same is also true of the two following chapters on Sweet Peas for Indoor Decoration, and Seed Saving. Lists of suitable varieties are given in the closing pages, with advice on their selection, which all amateurs will find of the greatest assistance. In the last chapter the author attempts to peer into the future, and comes away hopeful that the ideal sweet pea has still to appear.

Many half-tone illustrations appear throughout the book and add considerably to the value of the text; while the frontispiece is a good colour reproduction of three 1925 novelties from a painting by Miss West.

It is certainly a useful little handbook, which all gardeners will find of the greatest service, and it is well worthy of a place in one's horticultural library, as it will probably remain for some time the most up-to-date book on the culture of the sweet pea.

Obituary.—As we are going to press, we much regret to learn of the death of the Rev. Joseph Jacob, who died on Friday at the age of 67. He was a horticulturist of world-wide repute, and there was scarcely a flower in which he did not interest himself, and by his patient research and study improve greatly. An account of his life and work in horticulture will be given in the columns of our next issue.

We also learn with sorrow of the sudden death of Professor William Bateson, M.A., F.R.S., the director of the John Innes Horticultural Institution, Merton Park, Surrey. Dr. Bateson was educated at Rugby and St. John's College, Cambridge, where he had a distinguished career. For some time he was Professor of Biology at Cambridge, and was appointed to the directorship of the John Innes Institute in 1910, which post he held until his death. Scientific literature has been enriched to the extent of several valuable contributions on Evolution and Heredity, and his untimely death ranks as a severe loss to the botanical as well as to the horticultural world, for which he laboured patiently for so long.

TWO PLANTS WORTH RAISING FROM SEED

ROMNEYA

AMONG the aristocrats of the garden is Romneya Coulteri, the tree poppy, a handsome perennial with magnificent silky white petals somewhat like the poppy. This plant is difficult to transplant, and it is always obtained from the nursery in pots, but intending growers need not overlook the fact that it can be raised from seed.

Contrary to the general opinion, it is not very difficult to raise plants by sowing seed in a cool greenhouse. The seed is almost invariably slow to germinate, but it will come up pretty freely in time, and the seedlings need nothing particular in the way of extra care. Some of the plants, indeed, may flower the first season. It should be noted, too, that they can be grown on in pots in the greenhouse provided that there is space enough for them to develop.—HUGH AITKEN.

GERANIUMS.

A few seedsmen offer geranium seed, and those who are fond of a little experimental work, and have time to fulfil their inclination, may try raising these plants from seed. Occasionally it is possible to have blossom within the year, but unless a warm greenhouse is available they have to be kept over until the second season.

Seed may be sown at any time in spring or summer, beginning in February. The ordinary plan is followed out, the seed-pan being placed in a warm corner of the greenhouse until the seedlings appear. These may be transplanted into a box when sizable.

When the seedlings are sufficiently large they should be transferred to 5in. or 6in. pots, a compost consisting mainly of fibrous loam being used. They are planted firmly in this and, when growth has begun, pinched back to promote bushiness. From a sowing made at once plants will be ready for the open border by summer. They are unlikely to flower, however, until late in the season. If flowers are desired, they may be grown on in pots in a sunny frame. Border plants may be lifted carefully and flowered in the greenhouse during winter.

As a fair percentage of the seedlings will come true, only the best seed should be sown. It is rather interesting to raise a batch of plants, and as a packet of seed is not very expensive, gardeners can in this way quickly work up a good stock of plants.—CLYDESDALE.

FLOWER GRASS

THE idea of growing small, brightly coloured annuals amid lawn grass is really Japanese, and in this way a very charming effect is produced. A special bed in an open situation is set aside for the flower grass, and the soil should be well prepared. The flower grass mixture is prepared for sowing in this way. To each ounce of lawn grass seed is added a pinch of a number of annuals. Care is needed to select those plants which

The above are a gorgeous range of colour
WRITE FOR CATALOGUE (FREE) of all the best Sweet Peas for 1926. Also pedigree vegetables and choicest flower seeds
HENRY ECKFORD, Headquarters for Sweet Peas, Dept. 81 Wem, Shropshire

are fairly small and of a delicate habit, and yet will produce an abundance of showy flowers. Good subjects are found in several kinds of flax (linum), Virginia stocks, nemesias, brachycome, etc. A thorough mixing of the grass and flower seeds is essential, and the sowing should be carried out rather lavishly. The idea is to get the entire bed covered with a mass of grass interspersed with the flowering plants. Any of the flowering subjects that grow too strongly might be pinched back or, in exceptional cases, removed altogether. One thing to be borne in mind is that a good amount of moisture is needed to make a flower grass bed a success. In dry weather water freely, and then the bed will remain a thing of great beauty for a very long time.—S. L. BASTIN.

THE HARDY PLUMBAGO

A VERY valuable plant for placing above the upper edges of rocks or slopes in the rock garden is the hardy plumbago (P. Larpentæ). This dwarf herbaceous species is perfectly hardy and, as a native of northern China, can withstand a great deal of cold. The plant sends up wiry stems which form neat tufts from 6ins. to 10ins. high. In early September the upper part of the plant becomes nearly covered with bright blue flowers which, as they go off, turn to a pretty violet tint. The hardy plumbago will continue flowering until a late date and, in sheltered positions, it will often keep up a display of bloom until November. The species should be given a little consideration in the matter of soil and position. A warm sandy loam is the best, and to secure a really fine display of bloom a sunny situation must be selected. Any considerable amount of shade will very much affect the free-flowering that makes this plumbago so desirable. The species is easily propagated by divisions of the roots during winter or early spring.

Launching an offer of Seeds for trial.

Free and Post Free.

We launch this offer with much the same feeling in which we should approach thin ice—gingerly—because the offer might be thought to somewhere hide the cloven hoof.

But as we are neither asking for money nor making any conditions whatever in offering to send seeds free to anyone who cares to ask for them, it is difficult to see where the hoof could be hidden.

In the hope of getting into touch with a larger number of gardeners than we now have the pleasure of serving, we are sending to all applicants, free and post free, one packet each of three remarkably good vegetable seeds:

BEETROOT—BAKERS' SELECTED GLOBE. A beautifully formed round beet with a conspicuously thin tap root. . . . .

PARSNIP—GOLIATH. The biggest and best Parsnip that has ever come our way. . .

ONION—MONARCH. The largest growing, best flavoured Onion among those that really keep.

All we ask is that only responsible people will send for the seeds and that they will do their best with them when they get them, because it is only on results that we can hope for the distribution to benefit us.

Where results are good we hope that the grower will be encouraged to learn for himself what Bakers' other seeds are like and so bring grist to our mill.

For our part we can assure all such ladies and gentlemen in advance that the behaviour of the three varieties of seeds we are sending may be taken as a trustworthy guide to the growth and production of all the seed we sell.

Bakers
SEED & FLOWER FARM,
CODSALL.
Nr. Wolverhampton.

To anyone who is diffident about sending for the free seeds we shall be glad to send a copy of our complete Seed Catalogue. In many ways it is an unusual list—more informative than most—certainly more comprehensive and with something about it that might be called the "human touch," as distinct from the cut and dried, soulless sort of production most of us are used to.

Real Cambridgeshire grown Fruit Trees, Fruit Bushes, Roses, Shrubs, Avenue Trees, Privet, Plants.

Exceptionally strong and healthy.

FRANK RICE (F.R.H.S.), Arbury Nurseries, Cambridge

Seedlings Thrive and Don't Die

off after being transplanted owing to root disturbance or breakage, if brought up in Patent

MILLIONS SOLD **T. P. SEED RAISERS** NO SLUGS

because no disturbance can take place.

FOR ANNUALS, as Godetias, Clarkias, Larkspur, etc., *USE* BABY T.P. SEED RAISERS (measuring 1¼in. across by 2in. deep). Sow 2 or 3 seeds per Raiser, pull out to strongest. It will develop strong root growth till planting-out time comes, when Raiser (by that time rotted) will peel off, allowing seedling to be put in soil without knowing it has been touched.

FOR SWEET PEAS *USE* T.P. PEA RAISERS (size 1¼in. across by 4½in. deep). Sow 1 seed per Raiser. You will be delighted with good root action and quick development after planting out.

You get stronger plants, guaranteed to grow well with less labour.

T.P. Raisers take up much less room and retain moisture thus requiring less watering, are easy to handle in bulk and do not break, and ensure good plants, thus saving seed wastage.

PRICES in U.K., cash with order, carriage paid—

Baby "T.P. Seed Raisers, one strong seedling tray with 54 "**Baby**" Raisers complete. 1 for 2/6; 2 for 4/9; 3 for 6/9; 6 for 13/-; 12 for 24/6. **Refills** ("**Baby**" size), 108 for 2/7; 216 for 4/10; 324 for 7/3; 540 for 11/3.

LONDON, W.1

SOME RECENT PUBLICATIONS.

WITH the great increase which has taken place in all phases of gardening during recent years, there has come, hand in hand, a corresponding increase in the output of all manner of horticultural books. One or two of these make their appeal to the botanist more than to the gardener, but the keen horticulturist will find in them much to interest and instruct him and perhaps even to criticise, if he be of that turn of mind.

Among the many recent publications it may be of some assistance to those who are on the look-out for new works, to sift out a few which can, with profit, be added to the library. Not a little care is required in the selection of books which will instruct and yet at the same time provide recreation and enjoyment.

Messrs. Thornton Butterworth have published two or three additional volumes in their Home Garden Book Series and these deserve the attention of every amateur. They are written by one who has a wide, practical knowledge and experience of horticulture in this country and the information given in their pages can be relied on. The one devoted to the culture of Gladioli is especially good and those who are going in for the culture of this excellent flower will find the book of great assistance. Others from Mr. Macself's pen, which will make their appeal both to the general gardener and to the specialist, include "Bulb Gardening," a treatise on the growing of all classes of bulbs, and "Soils and Fertilisers," which contains many hints on how to get the best out of the soil and the treatment of pests which frequent the garden.

To all who garden, either in a large or small way, the choosing of plants to fill the hardy flower border is probably one of the most pleasant and engrossing of all gardening duties. The selection of suitable inmates for and the planting designing and stocking of the herbaceous garden are questions fraught with many difficulties and to these the amateur grower of herbaceous flowers will find a ready and satisfactory answer in two volumes. One is the new and enlarged edition of "The Herbaceous Garden," by Mrs. Philip Martineau, published by Messrs. Williams and Norgate, price 12s. 6d., while the other is a small volume, but no less serviceable, "Herbaceous Borders for Amateurs," by R. V. G. Woolley, published recently by *Country Life* at 5s. Both will be found to supply all the knowledge that is necessary in connection with the planning and planting of this part of the garden.

The fruit grower will also find two recent books to interest him. The Lorette system of pruning has been set forth for the benefit of all British growers in a recent translation by the late W. R. Dykes, of Louis Lorette's work, published by Messrs. Martin Hopkinson and Co., at 7s. 6d. This work ran through four editions in French and it is almost certain that it will be equally popular in this English edition. The other is the second volume of Mr. E. A. Bunyard's work known as "A Handbook of Hardy Fruits." This, the second and last volume, contains the descriptions of all stone and bush fruits to be found in cultivation throughout the country.

(To be continued).

A New Book Every Sweet Pea Grower Should Read:

"SWEET PEAS: THEIR HISTORY, DEVELOPMENT AND CULTURE."

Price 5/- net. *(Postage 5d.)*

By CHAS. W. J. UNWIN.

THIS new book will be enjoyed by all who love or grow Sweet Peas, indeed by all flower lovers. Every phase of up-to-date culture for all purposes or objects is treated in detail. It is brimful of interest and practical assistance from cover to cover, and admirably illustrated with photographs, a coloured plate and sketches, while its scope embraces all aspects in detail which are likely to help any and every amateur grower and exhibitor.

WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

CLAY'S FERTILIZER

The Gardeners best friend

GOOD SEEDS will never give of their best in poor soil. Help both seed and soil with **CLAY'S FERTILIZER** and then, together with nature, your garden will be a source of profit and enjoyment during the coming months.

CLAY'S FERTILIZER can be purchased anywhere at the following prices :—

Tins 10d. and 1/6

and in **Branded and Sealed Bags :**

7 lbs. - **3/6**	14 lbs. - **6/-**
28 lbs. - **10/-**	56 lbs. **18/-**
112 lbs. - **32/-**	

or if there should be any difficulty in getting it locally, we will send it direct to you from our Works, carriage paid in the United Kingdom for cash with order (except Tins).

Every Tin, Bag and Seal bears the Trade Mark.

CLAY & SON, Manure Manufacturers, Bone Crushers, etc. **STRATFORD, LONDON, E.15**

Three Sterling Novelties for 1926

Give them a trial and you will be more than satisfied.

NEW TEN WEEK STOCKS

Edwards' "Super Dreadnought"

This new strain of "Super Dreadnought" Stock grows from 25ins. to 35ins. in height, the giant double spikes measuring up to 18ins. It is branching in habit and early flowering, coming in flower in ten or twelve weeks.

I have great pleasure in introducing these "Dreadnought" Stocks to my customers. These will be grown all over Great Britain this season. And I should like you as keen gardeners to try a collection, they are bound to win prizes.

APPLE BLOSSOM.—A lovely shade of blush pink, very fine.
DORIS.—A very lovely ivory white, shaded old rose good habit.
DOROTHY.—A giant lavender, a splendid shade for florists' work.
GOLIATH.—A very fine mauve, extra fine flowers
INDOMITABLE.—Magnificent fiery scarlet, certainly splendid.
LEVIATHAN.—Lilac, massive spikes.
MARS.—Deep crimson, very good.
NEPTUNE.—The darkest Blue Stock, splendid shade.
PICTURE.—A magnificent cream pink that everyone will want.
SNOWDRIFT.—This variety is a champion, being pure white.
SUNLIGHT.—A lovely shade of yellow, very good.
TOPSY.—A most lovely shade of rose pink.
MIXED.—Special hand mixed, being made up of equal proportions of the above-named varieties.

All above, **6d.** per packet.

NEW SECOND EARLY PEA

Edwards' "Fifty-Five"

To all my customers I would recommend a trial of this New Second Early Pea "Fifty-five." It is rather an early second, coming along almost immediately after Sherwood, and as a succession to my Twelve Inch, is very good. "Fifty-five" is only 18ins. in height, and is one of the heaviest cropping Peas I have ever seen, its dark green pods are closely packed with peas of a fine dark green, full Marrowfat flavour, and usually about seven to nine peas in a pod; the pod itself is slightly curved, and it is not exhibition size, but as a *utility* pea I believe it has a splendid future, the haulm being literally covered with pods. I am sure that a trial will convince all that "Fifty-five" is the heaviest cropping Dwarf Second Early Marrowfat Pea.

Per pint **2/-**

NEW ONION

"Ipswich Champion"

This New Onion is the heaviest type of Exhibition Onion there is on the market, raised by an exhibitor and shown at the largest shows in Great Britain, where it has always taken prizes. The stock of seed is rather limited for this year, and I cannot offer by the ounce.

This Onion will grow to 3½lbs. in weight, and all onion exhibitors must give it a trial. Per packet **1/-** and **2/-**.

Send for Complete Seed Catalogue, post free.

AUTUMN and WINTER BEAUTY

In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.

In the *Field*, a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6.

THE LATE REV. JOSEPH JACOB, M.A.: AN APPRECIATION

A GREAT gardener has passed away in the person of the Rev. Joseph Jacob. He was for forty-two years the Rector of Whitewell, a small parish in the diocese of Chester, but actually situated in Wales, a portion of Flint separated from the rest of the county by an intervening stretch of Denbigh. At the time of the Dissolution of the Church in Wales, a special clause was inserted in the Act to except Whitewell from its operation. In this peaceful country parish, with so few inhabitants, the bachelor Rector devoted his spare time to horticulture.

The Rectory garden was developed on the lines of a Dutch nursery garden, and the good soil and skilful cultivation it received produced fine quality in the many bulbous plants grown there. Daffodils and tulips were the chief subjects, grown in thousands in the large areas enclosed by high hedges of conifers and privet. After the eelworms threatened the vigour of his daffodils he arranged for them to be grown on other land, and gave more space to tulips. He was always ready to try the merits of new varieties, both for outdoor work and also under glass, and few men had such a wide knowledge of the garden value of so many varieties of these two genera.

During the last ten years he had been remarkably successful in raising seedling lachenalias and freesias, many of which received awards at the Royal Horticultural Society's shows.

He was a frequent visitor to the Dutch bulb fields, and his judgment and advice were much valued by his many horticultural friends in Holland. Delphiniums and asters were among the plants he had lately chosen to collect and compare, but most plants of value for garden ornament and cutting received a share of his attention. He made a point of trying a certain number of annuals that were but catalogue names to him each year, in order to learn their possibilities, and very few came under his care without his discovering some variation and line of improvement in the strain. By these practical methods he obtained a first-hand knowledge of ornamental plants which his facile pen poured out in a constant stream for the guidance of others. He wrote in an easy conversational style, enriched by a wealth of quaint or humorous quotations gathered from the most varied sources.

No one equalled him in this power of describing the qualities of flowers in amusing and vivid similes and anecdotes. Besides writing regularly for several horticultural journals, he wrote the gardening articles in the *Queen* for many years.

THE LATE REV. JOSEPH JACOB, M.A

He was the author of the two books in the "Present Day Garden" series, entitled "Tulips" and "Daffodils." As lately as 1924 he launched a useful book of simple information for the unskilled gardener, called "Hardy Bulbs for Amateurs."

His greatness as a gardener arose from his first-hand knowledge of the subjects he dealt with and his power of expressing it in everyday language. These two qualities made his name familiar to amateur gardeners throughout the world.

He was a member of the Narcissus and Tulip Committees and also of the Library Committee of the R.H.S. His own library contained fine copies of many beautiful and rare gardening books. His cheery manner and kindness of heart endeared him to all who knew him, and he will be greatly missed by a large circle of friends.

SHRUBS FOR UNDERPLANTING

THE FURNISHING OF THE GROUND BENEATH TREES AND IN OTHER UNFAVOURABLE POSITIONS WHERE OFTEN IT IS TOO DARK OR OTHERWISE UNSUITABLE FOR EVEN GRASS TO FLOURISH, WILL BE A SUBJECT OF INTEREST AND CONCERN TO MANY READERS.

IN most gardens there are positions unfavourable for the culture of shrubs in general, but which, with a little care and experiment in the choice of material, may be made interesting and ornamental. The planting of the ground beneath trees and the furnishing of dark corners, banks and slopes means very much in the general appearance and attractiveness of the garden, pleasure grounds and ornamental woodland. For the least favourable positions it cannot be said that the number of suitable shrubs is very extensive. On the other hand, it is a subject worthy of experiment in the planting of probable or possible subjects.

Common ivy is the subject most extensively grown beneath both evergreen and deciduous trees, also to furnish slopes and dark corners. Variety should be added by planting a number of the most distinct green-leaved varieties, and the flat character relieved by the introduction of some of the tree forms. Six of the most distinct and useful are Hedera canariensis (syns. H. algeriensis and H. maderensis), H. colchica (syns. H. Roegneriana and H. amurensis) and var. dentata, Emerald Green, H. Helix var. arborescens and H. colchica var. arborescens. Ivy should only be planted under common trees, as the roots are gross feeders and impoverish the ground, so that it is a fight for food and moisture between the roots of the two.

Among the taller evergreens the aucuba is the great stand-by for the darkest and least favourable positions. It is very surprising at times to observe the growth of these hardy fleshy-rooted shrubs in dark positions and in dry or root-infested ground. The spotted-leaved varieties are the most commonly cultivated, but, in particular under trees, the rich green-leaved sorts are the most pleasant and effective. Some of the best green-leaved forms, all varieties of Aucuba japonica, are, *Male*: viridis, grandis and crassifolia; *Female*: viridis Hillieri, longifolia, salicifolia, and the two dwarf varieties nana rotundifolia and vera.

The aucubas are so freely and readily propagated in quantity by cuttings in a close frame with gentle bottom heat that it is scarcely worth bothering about named varieties, but just to put in batches of cuttings taken from the best green-leaved forms at any season of the year when space is available in the propagating frames. Cuttings also root readily on a border outside, but the rate of progress is very much slower. Quite large shoots with several growths can be inserted in a propagating frame with bottom heat.

Prunus Laurocerasus is often seen planted extensively on sloping banks and under deciduous trees with clear trunks some distance up. Annual pruning is necessary to keep the plants within bounds and attractive. For prominent positions there are more interesting and ornamental shrubs to plant in preference to the common cherry laurel. Two dwarf varieties are, however, worthy of development for such purposes, their habit of growth and rich green leaves being just suited for dull and by no means inviting positions. The variety zabeliana is of somewhat spreading habit with leaves much smaller than the type, forming a freely branched shrub of attractive appearance. Stiffer in habit and notable for its hardiness, the variety schipkænsis is distinct and useful to plant in positions unfavourable to the majority of shrubs.

The mahonia or Oregon grape, Mahonia Aquifolium, is so well known that little need be written in its praise. For planting beneath tall deciduous trees it is second to none as an attractive undergrowth. To maintain a pleasant and neat appearance the plants should be

RHODODENDRONS CAN BE USED WITH FINE EFFECT UNDER THE SHADE OF TREES.

Digitized by Google

cut over each year in spring after flowering. Kept at a height of from 1½ft. to 3ft., according to the position, it provides a most beautiful and effective ground covering. The pinnate leaves on different plants and at various seasons provide many hues of dark metallic green; in poor soils copper and reddish hues are not uncommon. Nurserymen grow mahonias in thousands and ten thousands for covert planting. Division in spring and seeds provide easy methods of propagation.

As a dwarf flowering shrub to cultivate beneath deciduous shrubs and trees, the rose of Sharon, Hypericum calycinum, is an easy first in value. Rapidly increased by division, the plants thrive in nearly all soils and produce their rich yellow blossoms freely from June to September. Growing from 1ft. to 18ins. high, it is worth while cutting the whole growths back to within 4ins. to 6ins. of the ground each year in spring when new growths are about to push up. This gives a neat and tidy appearance, as the old growths harbour many old leaves during the winter.

Two species of ruscus are among the most valuable of all dwarf evergreen shrubs to plant beneath deciduous and evergreen trees. Our native butcher's broom, Ruscus aculeatus, is an erect shrub of stiff habit from 2ft. to 3ft. in height. The plants are unisexual, but my conclusion is that either the plants are not all unisexual or both sexes need not be present to ensure the production of the attractive red berries, ½in. in diameter, on the female. The free-fruiting forms are worth selecting and propagating by division.

Even more attractive as a carpet is Ruscus Hypoglossum, a dwarf shrub of spreading tufted habit, about 1ft. high, fresh shining green in colour. The furnishing effect is produced by the flattened branches or cladodes, which are leaf-like in appearance. The plants increase rapidly in size, and can be freely and rapidly propagated by division of the clumps.

MANY OF THE DWARF GROWING BERBERIS SPECIES FORM EXCELLENT CARPETS OF FOLIAGE UNDER TREES.

The shrub best known in our gardens is the shallon or salal, Gaultheria Shallon, a native of western North America. It forms dense thickets of growth varying from about 3ft. to 6ft. in height, spreading rapidly by means of underground stems or runners. The plants thrive best in moist lime-free soils. In moderate shade the plants produce globular pinkish white flowers during May and June, followed by juicy dark purple berries. Seeds provide a ready means of increase. Though the plants spread freely in the surrounding ground, increase by offsets or division is not so easy as one might expect. May is the best time for replanting, keeping the plants freely sprayed, and shaded with evergreen branches for a few weeks after planting.

The creeping wintergreen of eastern North America, Gaultheria procumbens, is a dainty dwarf evergreen 3ins. to 4ins., sometimes a little more in height. With its neat growth and glossy dark green leaves it forms an attractive carpet or undergrowth for deciduous shrubs and smaller trees, as, unlike most of the subjects named, it is not a gross feeder, neither is it equal to battling for food and moisture with the roots of elm or chestnut trees. Increase by division and by seeds contained within small red fruits nestling among the leaves in autumn.

For moist ground the Chinese Gaultheria Veitchiana is deserving of attention, in happy surroundings spreading by means of underground stems and forming a neat and distinct carpet. Its culture in dry positions should not be attempted, but it is noticeable that when planted in full sun the growths trail away in the directon of any shade and moisture if near at hand.

Among the newer Chinese shrubs the sarcococcas are particularly valuable additions, in view of their suitability to plant in shaded and partially shaded positions.

The one I like best is S. ruscifolia, quite a good name as descriptive of the rich dark green leaves. It should not be planted close, as then the distinctive bushy character can be seen, at least 4ft. through and 3ft. in height. S. humilis is of dwarf, tufted habit, 1ft. to 1½ft. high, giving a neat and pleasing appearance, planted as a carpet in shaded and sunless positions. S. saligna is an upright growing shrub with many slender stems, clothed with narrow, glossy, dark green leaves from about 2ft. to 2½ft. in height. All three species have small, white blossoms which commence to open sometimes before the close of the old year.

The Alleghany spurge, Pachysandra procumbens, forms neat tufts of growths

A GROUNDWORK OF HYPERICUM CALYCINUM USED WHERE GRASS WILL NOT THRIVE.

Digitized by Google

growing generally less than 1ft. high, making quite a useful and cheerful carpet for small areas. It is a native of the south-eastern United States. The other species, P. terminalis, is from Japan, with smaller leaves and some 4ins. to 6ins. high. The pachysandras are readily increased by division and like most of the shade-loving plants, thrive best in moderately moist soils.

We see frequent examples of the way the British brambles thrive in the woodland thickets and coppice. In fairly favourable positions the two double-flowered brambles, Rubus thyrsoideus var. flore pleno, white, and R. ulmifolius var. flore pleno (syn. bellidiflorus), pink, are worthy of attention. Under tall, deciduous trees with no low branches and soil not too dry, both plants give quite a good display of flower each year.

The privets, Ligustrum ovalifolium and L. vulgare, thrive in positions discussed in these notes, but one sees so much privet everywhere that one hesitates to suggest planting more, when there are other things equally suitable for the positions.

Rhododendrons ponticum and Cunningham's White, grow well under deciduous trees, but only flower when there is sufficient light to ripen the growths. Annual or biennial pruning is necessary to maintain a furnished and desirable effect.

CULTIVATION.

In view of the by no means favourable conditions for plant growth when the ground is already threaded with tree roots, a certain amount of preparation of the soil before planting is desirable to give the subjects selected a start in their fight for nourishment.

For the more shallow-rooted subjects, the ivy, hypericum, vinca and ruscus, a good dressing of rich soil should be forked in over the surface. A fork is suggested in order not to damage the existing roots too much if the trees are of value, but a spade can be used with advantage when the trees are large elm, horse chestnuts or limes as they will not suffer material damage. Assuming that the position will permit of the addition of 5ins. or 6ins. of fresh soil, such a top-dressing should give the undergrowth planted a good start.

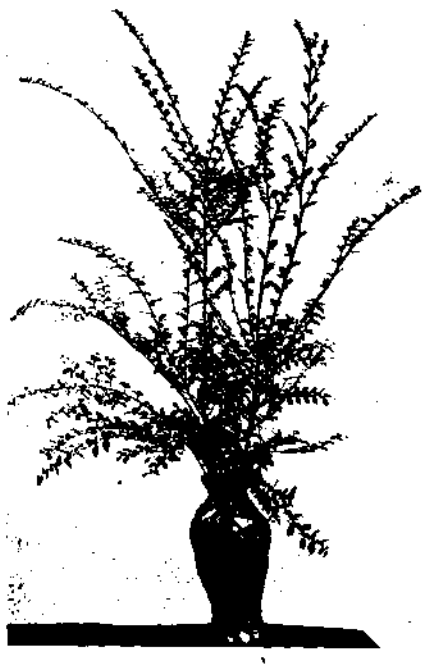
When fair-sized bushes of aucuba, holly or laurustinus are planted, it will be desirable to take out good holes for planting. This may mean the cutting of a few roots and may appear drastic, but it is necessary to give the new occupants an opportunity to gain a good root-hold or they will probably never become established and useful ornamental subjects.

Liberal supplies of water are most important, particularly during the first year or two after planting. With regard to mulching, discretion must be used as in some cases it may attract the roots of gross-feeding trees, which would do more harm than good to the subjects planted as undergrowth. A. O.

FOLIAGE FOR CUTTING

IT is during the winter months when the garden is barren, or almost barren, of flowers that one comes to realise how much can be done in the way of indoor decoration with foliage alone, always provided that a sufficient diversity in shade of colour and habit of growth is available. For instance, how admirably the grey-green—it is almost grey-blue—of Cistus ladaniferus contrasts with the deep green of Ceanothus Veitchianus, the pale, yellowy tipped sprays of Abelia uniflora and the shining leaves of Berberis buxifolia. And if to these are added some trails of Vinca major and of small-leaved ivy and the whole arranged lightly in a tall blue Chinese jar, the effect will be delightful. Here is another recipe. Take a few small branches of Veronica angustifolia, of Olearia Haastii and of Ribes speciosus (otherwise R. fuchsioides), mix with them some tall spikes of rosemary, half a dozen of the curving dark-leaved sprays of Berberis stenophylla and some trails of Hypericum calycinum, on which the pointed red-brown seed pods remain, place them in a big, two-handled cider mug of brown earthenware—and enjoy the result!

The tiny sweet scented blossoms of Azara microphylla are not only inconspicuous in themselves, but are so hidden away at the back of the branches that its value as a flowering shrub is negligible, but its flat fan-shaped sprays of shining leaves are ideal for mingling with other cut evergreens. Another useful shrub not very generally grown is Berberidopsis corallina, but unluckily it is not quite hardy save in the south of England. Choisya ternata, the flowers and foliage of which are equally beautiful, needs a very sheltered place and a little root protection in winter in a cold district, but it is worth while to give it this amount of attention. The value of Garrya elliptica for winter cutting is well known, but in my north Somerset garden, which is open to the east, it is completely ruined by early frosts nine winters out of ten and this winter is certainly not the lucky tenth! Daphne pontica is chiefly esteemed for its flowers, the scent of which is strong and sweet, if rather sickly, but its pale green foliage on bright brown stems is very handsome.



THE FEATHERY FOLIAGE OF AZARA MICROPHYLLA.

Most of the shrubby veronicas supply good material for winter cutting; perhaps the best for the purpose, besides V. angustifolia, already mentioned, are V. Traversii and V. salicifolia. The slender, graceful branches of the latter are not only pretty in themselves, but in a winter of ordinary mildness they are rarely without a few of their delicate little flower spikes. The majority of evergreen berberises are desirable for our purpose, but I confess to disliking cordially B. Aquifolium (Mahonia), which is so often seen in florists' shops dyed a horrible magenta crimson. It is ugly enough in its natural condition, but when artificially coloured it is repulsive. Skimmia japonica owes its popularity chiefly to its brilliant red berries, but even without these (and as this shrub is dioecious, it often happens that where only one specimen is grown it bears no fruit), its neat tufts of light green leaves are sufficiently attractive. The escallonias are of doubtful hardiness, except in warm districts or near the sea, but where they thrive their foliage is excellent arranged in "bean-pots," especially that of E. floribunda, E. exoniensis and E. langleyensis.

A quaint little heath-like shrub, of which both leaves and stems are golden-yellow, is Cassinia fulvida, otherwise known by the terrific name of Diplopappus chrysophyllus. Its bright and unusual colouring makes a pleasant relief to the more sombre greens and it may be also used successfully in combination with those winter-flowering shrubs whose blossoms appear before the leaves, such as Lonicera Standishii, Chimonanthus fragrans and the witch-hazels, although I am inclined to think that these really look their best alone.

I do not entirely share Mr. E. A. Bowles' liking for variegated foliage—*vide* "My Garden in Spring"—but it has its uses. Trails of Japanese honeysuckle (var. aurea reticulata) will relieve an over-dark mass of green agreeably, while in the case of large groups the so-called white-washed bramble (Rubus biflorus) may be introduced with a like result. Euonymus japonicus vars. aureus and albo-marginatus, and the similar varieties of Osmanthus ilicifolia, are all more or less desirable, but there is one variegated shrub which should be severely avoided and that is the coarse and common Aucuba japonica. R. E. HEAD.

WALL GARDENING—II

IT seemed easy to cover this special phase of rockwork in one article, but really it was a forlorn hope to attempt. I succeeded only in building a single wall and the herbaceous bed on top. The garden I have in mind slopes steeply and is big. So we get to the intriguing game again.

At the far side of the herbaceous bed you make another path—wider by half than the first—and beyond that rear a second wall of boulders heftier still to carry up the true perspective. And this time I am thinking of what is to be planted on the brink of the stout wall.

You shall have marigolds, set in great clumps between alternate companies of lads' love and lasses' love. And what is lasses' love? you ask. It is lads' love's mate—a winsome thing of grey, crinkled fragrance that sends up golden flowers in late summer. Elsewhere they name her French lavender, but here on the moorlands they give her a title of beguiling poetry. Lads' love and lasses' love—and marigolds roaming in and out, like pages at their bridal—what more could man ask of any wall-top, except we have, too, English lavender ranked close behind them in massed clumps? Lads' love and lavender—lavender and lasses' love—if you fancy they can only lilt so pleasantly together in mere words, plant them along that bold rock-top, and wait for summer, and see the rhythm and the poetry come to eager life, palpable and real.

Behind the lads' love and lavender, if you are wise, you will plant mallows, white-flowered and pink in alternate clumps. And behind them again, every happy blue that the delphiniums have captured. And, in among them all, the old English golden rod will be ablaze in autumn, side by side with the white daisy, tall, wide-eyed, a St. Michael of flower-land who holds autumn's banner up to the advancing hordes of winter.

These delights suggest, somehow, that you begin to strew the rock face itself with garden thyme in great profusion. It is a gallant-hearted herb, friendly with rocks, and at time of bloom one thinks of heather in its pride, up yonder where the high moors look down on our lowland garden efforts. And among the thyme be spendthrift once more with double arabis and London pride and golden alyssum.

It is hard to describe in little space the months that go to the building of such a garden, reared in friendly combat with northern weather—hard to tell the spadework joy of good, teeming earth that knows the business you are engaged on. The wrestle with boulders, too—you and a henchman, brothers at the lifting—is a diverting pastime. These big rocks are such passive resisters and seem so brainless till you get them into place and bring the bride-flowers among them to teach their gaunt uncouthness how to blossom forth.

There is a third terrace yet to be built. Again you widen the next path—it is a broad roadway now—and rear a clumpier boulder wall. You need two men to help you by this time, and the three of you get so into tune with the adventure that meals and most things else are forgotten. But old folk-tales of the moors and glens are remembered as you work. You learn more of your dale in a week of this sort than a year of other kinds of intimacy could teach.

We talk to rocks as to giants defying us or to children—this when we have got them nicely poised on edge—needing indulgent guidance. And the rocks say nothing audible in return; but we know that they understand it all. So far, indeed, does this intimacy go that sometimes, when we have placed a boulder to our liking and stand back to admire him, we fancy that his ancient face breaks into a wrinkled smile, as if his vanity were tickled.

When you have reached the summit of this steep-climbing garden, where the meadow beyond roves out to the fells and the moor, you choose your last line of boulders with extreme care and diligence. Every man of them you have marked, one time or another, up the pastures, and hoped to have him for your own one day. And now you hear the wagoners come down the hill-track, their wains creaking on the brakes. They are bringing you, from far-strewn fields of rock, your chosen monarchs to the ground prepared for royalty.

A battle-field sort of time ensues. The boulders to be reared in place vary in weight from four hundredweight to a ton. The Greeks of old in their crisp, romantic way would have named the biggest "no small part of a mountain."

They seem no small part now, as we all get mixed up together—gardeners and carters, pulley-blocks and rocks that shiver on their chains, stray wagoners' dogs that talk noisily about an affair they do not understand. It is a marvel that nobody is hurt; but there's order under all the confusion, and the wagoners are skilled with pulley-blocks.

Until now you have worked steadily from the stream at the garden foot, making your way up the steep rise yard by hard-won yard. Your plan is altered. Instead of working from the last-made path, you go to the garden top, where the dry-built wall that divided it from the meadow has been taken down. Along the shallow trench, prepared already along the line of the old wall foundation, your biggest rocks are lowered into place, shoulder to shoulder, till they fence the garden on its windiest side far more effectually than the dismantled wall could do—defend it not only from gales and roving sleet showers, but from field seeds incontinently blown into your ordered plan of what should grow, and what should not, in the garden they assault.

The joy of seeing that outer rampart in settled order is not to be described in words. You have worked with such consuming zeal at the garden itself. What use would there be in that if you had left it to the mercies of a northern winter, shrilling from the hill-top? As well build a house, plant it with wife and weans, and fail to bar the doors o' nights.

A WALL GARDEN WITH NATURE'S CLOTHING.

At this stage of the adventure you are vastly practical. The stones of the discarded limestone wall have been wheeled into heaps this side the boulder rampart and broken into chips. Soil and leaf-mould have been barrowed into their separate piles. It is simplicity itself, with the men and tackle at command, to get the smaller boulders into place and fill their crannies with soil mixtures to your liking.

When all is finished, your terraces tier on tier are walled at the summit by a broad boulder garden which, viewed from the garden foot, is singular in its bold completeness. Seen close at hand it is a realm of its own, a fairyland of blossom and many-coloured leafage.

Before planting the top of this stout rampart you have studied old castle walls and learned what flowers will brave naked weather, provided you give

Digitized by Google

them the like foothold among the crannies —powdered rubble, a minimum of thin soil, nothing leaf-mouldy or rich. The plants that sentry castle walls, true to their military tradition, ask for no soft living.

This highest clump of boulders, which walls the garden, descends in rough ledges to the level of the path below. Once the exposed summit is planted with the hardiest subjects, one has a freer range of choice for the lower, sheltered ledges, and individual fancy may design at leisure. One boulder, however, makes its own suggestion. It has come from its pasture home ready planted, and a most alluring clump of ground ivy clambers about its face. Cotoneaster, too, thrives in the deeper clefts, and is a year-long joy. Flower and leaf and shining fruit are all delectable.

These for suggestions, too. When you reach the smaller boulders that step down to the path, build them a little wide apart and fill the pockets with good loamy soil, pebble drained under a liberal depth. Along the lowest tier plant every hue of violas known to the garden world—not anyhow, but each colour in its group. Violas anywhere are a physic for sore hearts. It is a revelation to see their maiden shyness, their velvet charm, against a background of hoar, grey rock.

So with the dianthus clan. On the ledge above the violas plant dwarf pinks in roving clumps. They are not shy at all, but eager lassies that welcome sun and shower. Violas in rain shed meditative tears, half sad; but the pinks shed tears of merry laughter. The two are good companions for each other.

And when your garden is complete, and summer blows, you may wander where you like in it, tasting its sweets. But always, I think, especially near gloaming, you will tarry longest on the highest path, and drink in the mingled odours of pinks and dewy violas. There is no fragrance so appealing, so swift to draw sad-happy memories and keep them near. HALLIWELL SUTCLIFFE.

ANNUALS IN THE ROCK GARDEN

THE use of annuals in the rock garden may not commend itself to every gardener, but it cannot be denied that the use of appropriate kinds for filling up or furnishing bare spaces is of great value for providing a display of colour during the summer and autumn months, after the great majority of alpine plants have flowered. Only the dwarfer-growing kinds should be used, so that they are in keeping with the other inhabitants of the rock garden. Many early-flowering plants used in the rock garden mature early and lose their foliage, as also do the bulbous subjects, leaving bare and unsightly spaces during the later months of the year. By the judicious use of annuals sown at the proper time this condition of things may be avoided.

Hardy annuals may be sown at any time from March to May for summer and autumn flowering. As it is not possible to dig between the permanent plants or bulbs, the soil may be prepared by loosening it with a hand fork, afterwards making it level and raking it finely. If the weather is dry, a good watering may be necessary some time before sowing. Sow the seeds thinly, and cover lightly with some finely sifted soil. Very fine seeds need hardly any covering at all, but the soil must be kept moist and, if possible, shaded with branches of evergreens till the seedlings are up. When the seedlings are large enough to handle, thin them out freely, leaving ample space for each plant to develop to its full size. When the thinning is well carried out, dwarf and bushy plants are the result.

Half-hardy annuals must be left for outside sowing until the beginning of May, and a warm sunny place should be selected for them. Among these are many plants with beautiful flowers of rich colouring, a representative one being Portulaca grandiflora, commonly called the sun plant. In the following selection of suitable annuals the majority are of dwarf habit, scarcely exceeding 3ins. or 4ins. high, or at most 6ins.

In the genus alyssum we have one valuable and charming little annual in A. maritimum. It is commonly called sweet alyssum and grows into a neat bush some 4ins. high, covered with fragrant white flowers. A form of this, called the rock alyssum, forms a carpet-like mass close to the ground, producing sheets of snowy white blooms. The seeds of this plant germinate in about ten days and come into flower in about six weeks. They should be thinned to at least 3ins. apart. With flowers of brilliant colouring is Anagallis linifolia, var. cœrulea having intense rich gentian-blue flowers, while var. Breweri has large brilliant scarlet ones. Campanula drabæfolia (C. attica) is a neat little plant with flowers about ½in. in diameter, those of the type being rich bluish purple with white centres, the other form having white flowers.

Somewhat taller is Cheiranthus Allionii, with its rich orange-coloured flowers produced in succession for a long period. A member of the lobelia family is Downingia elegans, also known as Clintonia pulchella. It is a native of California, and grows about 5ins. high, with blue and white lobelia-like flowers. The Namaqualand daisy (Dimorphotheca aurantiaca) is a beautiful annual from South Africa, with large daisy-like flowers of a glossy salmon-orange shade having a dark central ring in the typical plant. There are now many varieties of various shades of colour from blush white to yellow. Gilias are charming little plants of easy cultivation. They form dense tufts surmounted by numerous brilliantly coloured flowers. G. androsacea is one of the dwarfest, with rose-coloured blooms; while var. aureus has rich yellow ones. G. tricolor has lavender flowers shading to white, with a central violet ring. Various members of this genus are also known as leptosiphons.

A charming little Portuguese annual is Ionopsidium acaule, growing only 2ins. high. On the rock garden it may be associated with even the choicest plants, never overrunning its neighbours, while it is also valuable for sowing in the crevices of paved walks or rugged steps. It flowers very quickly from seed and often produces a second crop of its pale violet flowers in the autumn. Serving a double purpose as a decorative plant and a good bee flower, the Californian Limnanthes Douglasii is a free-growing annual, with beautiful yellow flowers, the petals of which shade off to white margins. It is of bushy habit, only a few inches high, and flowers for a long period. The linaria family contains many pretty annuals, some of the best being L. saxatilis with yellow flowers; L. maroccana, varying from dark violet to light blue, crimson and yellow; and L. reticulata with maroon-scarlet flowers having a golden blotch. One of the most brilliantly coloured annuals is Linum grandiflorum, with its large crimson flowers.

The Californian genus nemophila contains three or four very attractive annuals, the well known N. insignis being the brightest and best. Its flowers are bright sky blue with a white centre, and it is an inch in diameter. There is also a white variety worth growing, N. atomaria with white flowers, the petals of which are covered with minute spots; while in N. discoidalis the flowers have a deep maroon centre but are edged with white. Omphalodes linifolia is a very refined south European annual, producing throughout the summer months an abundance of forget-me-not-like flowers of a very pale blue or white. More suitable for the moraine is the alpine poppy (P. alpinum), a miniature plant with white, rose, yellow and orange-red flowers on slender stalks.

One of the very best blue-flowered annuals is Phacelia campanularia, which grows to the height of just over 6ins. The numerous flowers are bell-shaped and of the most brilliant ultramarine blue colour. They are produced over a long period. Belonging to the same genus, P. viscida, also known as Eutoca viscida, also has intense blue flowers.

Given a warm place in light sandy soil, the portulacas surpass all other outdoor annuals for brilliancy and beauty of colour. They are admirable for carpeting the ground in sunny situations, while the colour of the flowers varies from crimson and yellow through every shade to pure white. The individual flowers are large, and there are both single and double forms. Seeds are best sown in late April, and they quickly form large spreading tufts. Sphenogyne speciosa (also known as ursinia) is of dwarf spreading habit, with showy marguerite-like flowers on low-growing, spreading plants. The flowers vary from buff yellow to lemon colour, and are of good size.

Most certainly a few out of the foregoing list should find a place in the rock garden this year. W. I.

THE BLUE POPPIES—II

BY F. KINGDON WARD.

MECONOPSIS SIMPLICIFOLIA var. Baileyi is a fairly well known plant, but is not very happy with us. It mopes along, however. I have never quite understood why this sky blue flowered plant from the eastern Himalaya is considered to be distinct; Sir David Prain said that it was identical with the species known from Nepal and Sikkim, but growers decided that M. simplicifolia was a perennial with dark blue or purple flowers, and hailed the sky blue biennial with joy. It is only necessary to add that M. simplicifolia, as figured in the *Botanical Magazine* many years ago (Tab. 8364), has sky blue flowers and exactly resembles Sir Herbert Maxwell's excellent painting of M. simplicifolia var. Baileyi, reproduced in his latest book.

Nothing is said about scent in any of these plants. Our M. simplicifolia (K.W. 5737), collected in the drier country north of the Tsangpo, is delightfully fragrant; it may, or may not, prove easier of cultivation than previous gatherings. It wants half shade and a well drained soil, growing on banks under bushes for preference. A fairly rich mixture of half loam and half grit would suit it. We made two other gatherings of plants purporting to be the same thing, more or less, from south of the Tsangpo. K.W. 5855 looks very like M. simplicifolia, but it has wine purple flowers without scent, and a longer style; it comes from a lower altitude but a wetter region.

The third gathering, from the other side of the same range, K.W. 6245, we did not see in flower, as its haunts were under deep snow when we first visited them. It may well be a distinct species, though it is of the simplicifolia type and is also an alpine; but it produces twice as many scapes as our M. simplicifolia, six to eight as against three to four, and grows in the open on rubble chutes.

The only other species of this alliance it is necessary to mention is the ivory poppy, K.W. 5766, a very rare plant, seeing that we found only seven specimens of it. Moreover, it set practically no seed, so that it remains doubtful whether we introduced it or not. If it is an albino form of M. simplicifolia—which it closely resembles, even to the fragrance—it may come up with that plant; but if it is a distinct species—as some plants with pallid yellow, rather than white, flowers suggest—it is unlikely to.

The aculeatæ or prickly poppy group furnished two fine new species, M. Prainiana and M. Cawdoriana. The former, from rather lofty altitudes, grows 4oins. high and carries a fine raceme of pale blue nodding flowers with golden stamens. It is not scented. The flowers are rather more firmly put together than those of most aculeatæ, and do not so readily come unstuck in wind and rain; the result is that you get a number of flowers blooming at the same time, which is unusual with M. Prattii for instance, which soon begins to look draggled in bad weather.

MECONOPSIS PRAINIANA, ONE OF THE PRICKLY GROUP.

If M. Prainiana (K.W. 5909), which has come from seed moderately well, proves hardy, it will be a distinct acquisition; but its habitat—boulder screes at 15,000ft., — is suspicious.

M. Cawdoriana is a lovely thing with sweetly scented sky blue flowers and golden stamens. In habit it resembles the ordinary form of M. horridula—that is to say, there is usually no central stem, but a false stem, composed of fused solitary scapes, each of which bears a single nodding flower; most of the inflorescence is composed of these single-flowered separate scapes.

M. Cawdoriana does not range quite as high as M. Prainiana, occurring between 14,000ft. and 15,000ft. on turf or earth slopes, and flowering before the end of June, nearly a month earlier than M. Prainiana. Seed of it, K.W. 5751, has germinated, but not freely. Neither species is very common, though both are fairly widely spread. On one occasion I saw a remarkable sight, namely, five species of meconopsis in view at once, and there must have been several dozen plants there. The species were M. pseudo-integrifolia, var. M. simplicifolia, M. Cawdoriana, M. impedita var. Morsheadii, and the ivory poppy. As a rule—certainly in China—these plants keep to their own beat, and I have never before seen such profusion.

THE IVORY POPPY.

M. impedita var. Morsheadii, which differs from the type only in technical details, is the commonest alpine species in eastern Tibet. It occurs in thousands on the steep gravelly turf slopes, throwing up its little fountains of dark blue golden-eyed flowers, which open after the middle of June. It is a graceful little plant, but, since M. impedita has not proved very successful in cultivation, this variety may not fare any better.

It cannot be too strongly insisted that what all these plants chiefly need is a good run for their long tap roots. They ought to have at least 3ft. of loose soil, and no water standing at the bottom. It is all very fine growing them in the rock garden—they are, of course, rock plants; but we grow so many things there that in the dense rich soil used to feed them all, their roots cannot go down, and they are starved and stunted in consequence. The soil must be coarse, with a free admixture of sand or chips, and the plants must not be crowded up with a lot of other stuff. They should be scattered, preferably on a steep slope to ensure good drainage, and sheltered from direct sunlight. Some species, but not all, like lime, or are, at least, indifferent to it; but none of the species collected in Tibet requires lime.

Just as there are two things these plants demand—namely a sufficient depth of light soil and abundant water—so there are two things they will not put up with, summer drought and impure air. Both are fatal. All the species are gluttons for water, and almost live on it; never mind how poor the soil is so long as there is plenty of it, and plenty of water underneath it. As for impure air, the meconopsis are not town plants, and abhor smoke.

So far, success has chiefly attended the cultivation of the most strapping species, belonging to the group robustæ: M. Wallichii, M. paniculata and M. robusta. Of the prickly blue

Digitized by Google

poppies, M. Prattii and M. latifolia do well; and both M. integrifolia and M. pseudo-integrifolia offer no insuperable obstacle. But these are all biennial, and, though several of them come from self-sown seed, that is not so satisfactory. What we want is a good perennial, and M. Baileyi appears likely to fill the gap. As for the dwarf species—MM. bella, concinna, lancifolia and others—to most of us they are but names. Possibly the dwarf yellow-flowered M. Florindæ will satisfy our wants there too.

NOTES OF THE WEEK

KERRIA JAPONICA.

KERRIA JAPONICA is a favourite with quite a number of country folk and, not infrequently, is found growing in bush form near cottage doors, its orange-yellow blossoms being a feature of the garden in May and June. It is a shrub found in many parts of England, and seems somewhat indifferent as to soil, doing best, however, when planted in sandy loam. Unfortunately, too often it is permitted to grow as it pleases, no pruning being attempted, consequently one notices bushes full of weakly shoots. Best results are always obtained when some of the old wood is cut away after the blooming period.

We are apt to think of this old worthy of our gardens in the terms of bushes and overlook the fact that it is quite amenable to training over walls and around door frames. On a south wall, where the blossoms often open in May in an early spring, it makes a fine display. Kerrias will lift quite late in the planting season, and February and March is as suitable a time as any. To deal with it as a climber, a plant should be procured having two or three shoots.—W. F.

THE EARLY-FLOWERING RHODODENDRON PRÆCOX.

MANY people maintain that these early flowering rhododendrons are not worth growing in the open unless in very favoured districts, as they are liable to be spoiled by frosts at their flowering period during our erratic springs.

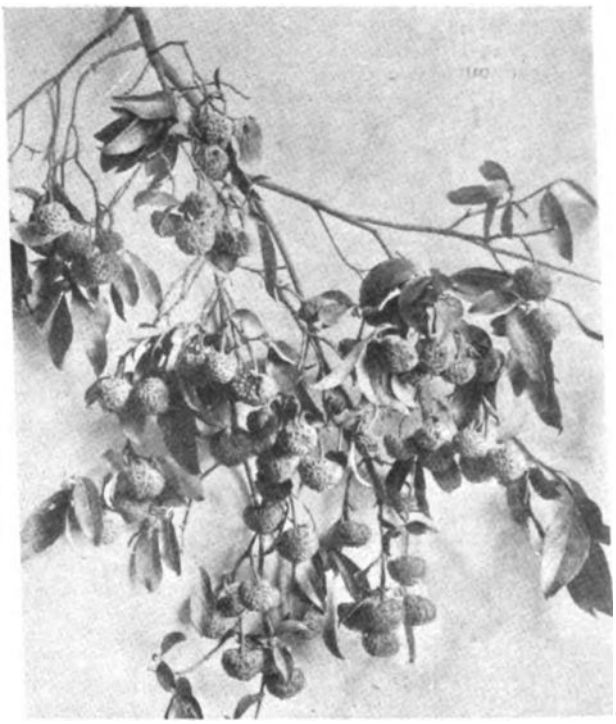
If a position sheltered from the east is chosen, where the early morning sun cannot reach them, they are subjects that may be enjoyed during most seasons, for at least a few days and very often for their full period of flowering. R. præcox, the subject of this note, is a hybrid raised from crossing the beautiful R. ciliatum with R. dauricum. In the north I have seen dauricum flowering freely during December and January, followed by præcox, moupinense and ciliatum.

R. præcox forms an ideal bush and no flowering shrub is more beautiful in early spring than this when covered with its rosy-purple flowers. It is quite hardy and is easily struck from cuttings of half-ripened wood inserted under bell-glasses in sandy peat, in a little bottom heat.

Greater use could be made of these small-flowered forms of this noble family in forming dividing hedges in districts where rhododendrons flourish. Such varieties as præcox, ciliatum, yunnanense, lutescens and ambiguum, might be much more used for this purpose and would form more interesting hedges with less trouble and expense in upkeep than some of the subjects we see used for this at the present time.

The illustration is of a plant of R. præcox which has been growing for a number of years in Greenwich Park, by no means an ideal home for rhododendrons.

Incidentally, it may be mentioned that many of the older residents of Greenwich and Blackheath pay frequent visits during early spring to this fine old park to note when the first flowers of "their" rhododendrons open and many have kept records of the period of flowering for a number of years.—R. FINDLAY, *Wisley*.

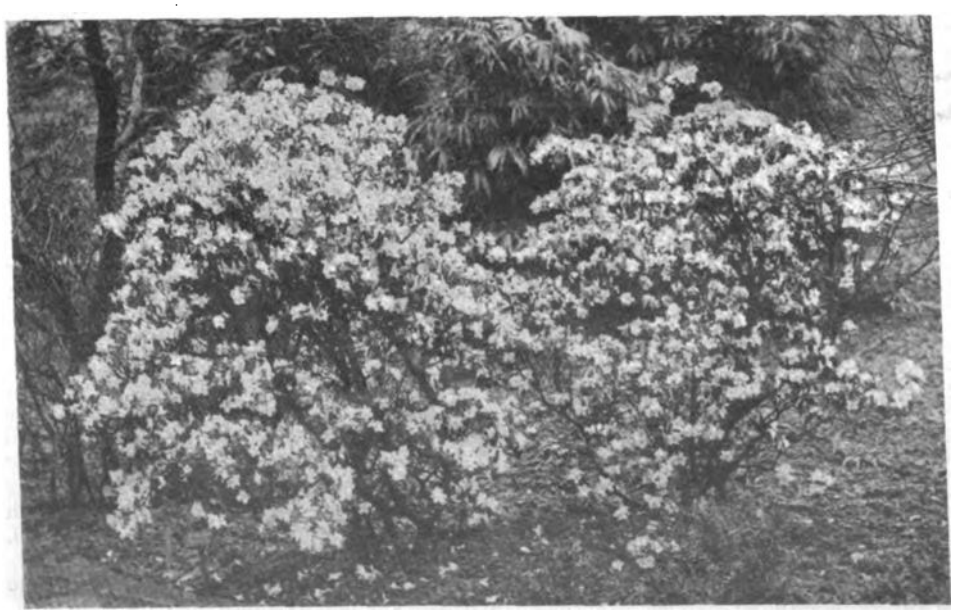


A FRUITING SPRAY OF CORNUS CAPITATA.

CORNUS CAPITATA.

IN many gardens this tree is known under the name of Benthamia fragifera, but the above is the correct nomenclature according to many authorities. Where it thrives C. capitata makes a handsome shrub and Cornwall is a favoured spot for this delightful plant. That, however, is not the only county where this plant will give tolerably good results, here, in Monmouthshire will be found several examples, 18ft. to 20ft. high and even more in diameter. The beautiful garden of Itton Court, Chepstow, can boast of a good plant, while at St. Pierre, Chepstow, the residence of Mr. D. C. Lysaght, there are two specimens, one of which is nearly 30ft. high and 20ft. across. This plant occasionally bears fruit freely and it was this source that supplied the material for the illustration. The strawberry shaped fruits are reddish-yellow and are readily seen in the picture, and although the shrub is attractive when laden with its fruits, it is even more so when in bloom. The actual flower is minute and inconspicuous, the beauty being in the four or six sulphur-yellow bracts. The plant is partially evergreen, the flowers appear in June and July, while the photograph was taken at the end of November by Mr. M. Moulton. It was introduced from the Himalayas a century ago, and it also hails from China.

This cornel cannot be recommended for every garden, but there are many in which it would thrive, flower and bear fruit. It will never succeed in a cold, wet soil, so a well drained position should be chosen.—T. W. BRISCOE.



RHODODENDRON PRÆCOX WREATHED IN BLOSSOM IN EARLY FEBRUARY.

CULTIVATED BLACKBERRIES.

IT may seem strange to some readers that I should recommend the above-named hardy fruits as desirable occupants of any garden, and it would appear quite unnecessary in districts where these berries grow wild on commons and in the hedgerows. I do advise their cultivation where space is available, as it is in hundreds of gardens. Odd corners and positions where practically no other profitable crop can be grown are suitable sites. It is done in my own district where there are acres of blackberries growing wild, and our own British blackberry is given the preference. When the plants are well grown and properly trained, fed at the

Digitized by Google

roots while the fruits are swelling and allowed to mature thoroughly, they are almost as large again as the wild ones, the aroma from the growing berries and while they are being gathered is delicious, and less sugar is required when jam is made. The fruits are borne on wood grown during the previous year, except in the case of the Himalaya Berry, a new blackberry which bears on old wood for several years. The Wilson, Jun. and the variety Lauciniatus, commonly called parsley-leaved, are the two sorts in addition to our native berry that deserve cultivation, but I think the flavour of the last named is the better. In every case the plants should be quite 6ft. apart. I do not favour trellis-grown plants, as it is so difficult to disentangle the shoots. Train to upright stakes about 7ft. high. When the fruit has been gathered unfasten the branches, let them fall to the ground, cut out the fruit-bearing ones, and retrain three or five to the stake again and the work is done. The plants never get out of hand. Cultivation: good, firm soil and feeding as stated above.—GEO. GARNER.

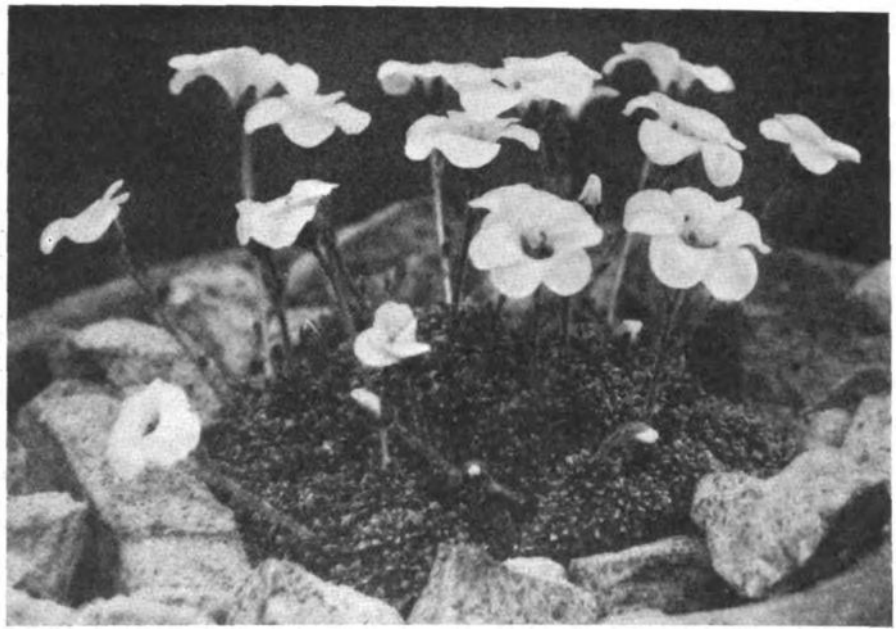
DIANTHUS GRANITICUS.

MANY admirers of the dianthus care little for the small-flowered species, such as D. deltoides, the "Maiden Pink, of odour faint," but a considerable number of these create quite a good effect when massed together, and when so grouped are by no means to be despised. Our own maiden pink has great beauty: but its ally, Dianthus graniticus, from the granite districts of the Pyrenees and southern France, is of even more value for massing in the rock garden or on the moraine. It may, with some truth, be called "a glorified maiden pink," from the taller growth and the superior size of its flowers. It has been said by a good and well informed critic that it is the best of the pinks allied to D. hirtus, and it is no mean tribute to its beauty to say this.

It is sometimes about a foot high, but is generally less, and with me has usually ranged from 9ins. downward to about 6ins. It has a slender, wiry habit of growth and the plant itself is quite pleasing. Above the tufts of leaves there appear, all the summer through, pretty, bright, notched, starry pink flowers, with the "freckling" observed on D. deltoides, which is almost zone-like in its way, and which is more evident on the white forms of D. deltoides than on the pink. While the general colour of D. graniticus is bright pink, seedlings vary considerably, and deeper coloured and also white varieties are produced. An excellent way is to sow a packet of seeds, which are offered by such firms as Messrs. Thompson and Morgan and to select the best seedlings for propagation by cuttings. A sunny place in a non-calcareous soil is the best for D. graniticus, but it does not resent lime to the extent of refusing to grow and flower, though it is not so fine when this ingredient is present in the compost.—S. ARNOTT.

A REMARKABLE STREPTOCARPUS.

ONE of the most remarkable of the genus streptocarpus is S. Wendlandii. This species, which was introduced from Natal in 1890, is an extremely handsome plant, with flowers of a bright and very clear blue colour. Probably the most arresting thing about the plant is its foliage, which usually consists of a single leaf of a very large size when compared with the plant as a whole. The leaf has given rise to the name of "Elephant's Ear," by which S. Wendlandii is commonly known in Natal. This streptocarpus is of simple greenhouse culture. Raised from seed sown in gentle warmth in the spring, the little plants are subsequently pricked off and potted as necessary.



A BEAUTIFUL NEW HYBRID SAXIFRAGE, S. ADA.

Every attempt should be made to produce sturdy specimens. It is important that, in the young state, the plants should never be allowed to become dry or be exposed to cold draughts. Either of these conditions are very likely to lead to failure.—S. LEONARD BASTIN.

SAXIFRAGA ADA.

THIS beautiful and very charming new hybrid—the result of a cross made between the neat-habited S. tombeanensis and the well known and delightful S. Burseriana crenata, by Mr. R. V. Prichard, who was, until recently, a member of the well known firm of Maurice Prichard and Sons, Christchurch, Hants—is a welcome and praiseworthy addition to this large and popular race of rock plants.

A distinguishing feature about this new hybrid is its early-flowering quality, for its many white buds, which are a trifle tinted with lilac, sit very tightly and complaisantly above their grey-green mounds throughout December's dark days as though to await the coming of another year before unfolding to the full the delicacy of their studded blossoms.

Better than words of mine could express, the accompanying illustration of a plant barely 3ins. across depicts its neat and compact habit, and the superb substance of its well formed, rounded and slightly recurved flowers, which are carried on slender, 2in. high stems. Its floriferousness and the length of time the flowers last leave little to be desired. Out of doors a piece of glass is very necessary in order to protect its early blooms from unkindly elements.—J. T. H.

AN INTERESTING AND WELL-FLOWERED STREPTOCARPUS.

Digitized by Google

THE FIRST SIGN OF SPRING

SIGNS were not wanting at the Royal Horticultural Society's Show at Vincent Square Hall on the 9th inst. that we are approaching the fringe of spring, despite the dull weather conditions then prevailing. A representative collection of exhibits was staged, embracing all the precincts of the garden. Alpines were a feature, while greenhouse flowers contributed in no small measure to the delightful colour effects. Many exhibits of fruit were to be seen, while there were also several collections of artists' pictures on view.

Messrs. Sutton and Sons of Reading staged a very fine collection of greenhouse primulas. The exhibit included numerous varieties of P. sinensis and its form (if it may be called a form) P. stellata. The plants appeared robust and of vigorous constitution, and the wide range and gradation in colour were most marked. The collection served to illustrate to those unaware of what is going on in the horticultural world in the way of hybridising the rapid advance which has been made with this particular flower in recent years. The plants were shown to advantage in a carpet of moss where the flowers and foliage could be appreciated to their full extent. The giant-flowered types always attract attention, and one in the collection of outstanding merit was Giant Intensity, of good colour and habit. The eyeless type, of which there is nothing else like it, is especially dainty, and is reminiscent when in the mass of gently falling snow. Brighter tones were provided by the warmer coloured Etna, with its dark foliage; Vesuvius and Ruby Star; while blues were to be found in Reading Blue and The Czar. There is no need for the greenhouse to be dull and without bloom when so many varieties of winter-flowering primulas are at hand to occupy it in association with cyclamen, one of the most admirable winter-flowering subjects for the greenhouse.

The most interesting and unique of all the exhibits was a fine collection of citrus fruits and ornamental gourds, shown by Mr. Cecil Hanbury. All these had been grown at La Mortola, Ventimiglia, Italy. Oranges, lemons, citrons and tangerines in many varieties, some with thin smooth skins, others with thick dimpled rind, were exhibited. The curious shapes and forms of the ornamental gourds were commented on by many a spectator. Messrs. T. Rivers and Son also showed an attractive group of oranges, but in this case pot-grown trees were bearing the fruit. Each tree carried a number of exceptionally large and well ripened fruits. Two large collections of apples, including many varieties, were exhibited by Messrs. Bunyard and Messrs. J. C. Allgrove. On both stands the fruits were still in excellent condition.

Messrs. Carter and Co. arranged an imposing exhibit of single early-flowering tulips grown in pots and bowls. The tulips were not only well grown, but tastefully and effectively set up in separate groups of blending colours. Included in the collection were General de Wet, a delightful shade of soft orange; Sir Thomas Lipton, a showy brilliant scarlet; Montresor, a well shaped clear yellow tulip; Queen Flora; Ibis; and Prince of Austria.

Some beautiful pot specimens of camellias wreathed in blossom of white and varying shades of pink and red, were exhibited by Messrs. Chaplin Brothers. The Swan was a most attractive single white; Corallina, a deep red; Lady McKinnon, a red and white variety; and Eugenie Messine, a charming soft pink. Fine specimens of the climbing rose Lady Hillingdon came from Mr. Elisha Hicks' Nursery. Mr. George Prince also showed roses. Rhododendrons and poppy anemones gathered from the open border were exhibited by Mr. R. Gill. Fragrant violets were displayed by Miss E. Heathcote and Mr. J. J. Kettle. Bright patches of colour were formed by the fine carnation exhibits of Messrs. Stuart Low, Mr. C. Engelmann and Messrs. Allwood Brothers. Greenhouse shrubs and flowering plants were exhibited by Messrs. L. R. Russell and Messrs. Stuart Low, the latter firm staging some fine hippeastrums. The topiary trees of Mr. John Klinkert formed a sombre group. Miss Frances L. B. Bunyard and Miss C. G. Trower both exhibited excellent drawings.

The alpines were shown in greater numbers, but in much the same variety, as at the last show. Messrs. Cutbush made a gay and fantastic garden round a standard wistaria, a pink azalea and Andromeda japonica, with groups of Iris reticulata, Cylcamen ibericum and Bulbocodium vernum.

F. G. Wood of Ashtead made a minute paved garden round a rose bed of Rosa Rouletti, backed with double primroses which included the rare A. Dunollin and the very beautiful but difficult Mme. Pompadour.

Clarence Elliott showed a mass of Saxifragas oppositifolia alba, Faldonside and Irvingii; a large, vigorous plant of Saxifraga diapensioides; Primula Winteri; and the true Bellis sylvestris, a tall crimson daisy, against a background of dwarf conifers.

Messrs. Barr showed a variety of dwarf irises of the pumila section, a striking cherry crimson form of Tulipa pulchellus, and some good named forms of Helleborus orientalis and its hybrids.

Messrs. Prichard showed Primula Winteri, which is becoming more and more popular now that its special requirements are known, and the very large-flowered form of Saxifraga oppositifolia.

Messrs. Reuthe showed the pale blue form, Cantab, of Iris reticulata, large masses of Cyclamen Coum, Polygala rhodoptera, a very compact, thick-leaved rock shrub from the Balkans, and the most beautiful of all hybrid crocuses, C. Celeste (C. ærius × C. biflorus).

Orchids are usually staged in abundance on the day of the Annual Meeting, and the show on this occasion was well up to the average. Messrs. Charlesworth and Co., Haywards Heath; and Messrs. J. and A. McBean, Cooksbridge, Sussex, were both awarded silver-gilt Banksian medals for extensive groups. The former firm showed several of their new odontonias, conspicuous on account of the broadly developed labellum; also Brasso-Cattleya British Queen, with three immense flowers; the handsome Dendrobium Gatton Monarch; and a wide selection of odontoglossums and lælio-cattleyas. The latter firm staged several excellent cattleyas, including a pure white hybrid named Brenda, and a fine specimen of C. chocœnsis alba, with six flowers. A showy plant was seen in Cymbidium Alexanderi, carrying forty-eight flowers, and some richly coloured hybrids in Lælio-Cattleya Smilax, of cinnabar red.

Messrs. Cowan and Co., Southgate, had many select cattleya hybrids in their group, prominent examples being Clotho, Enid and Tityus; while cypripediums and a many-flowered spike of Oncidium Cavendishianum gained for them a silver Banksian medal. A similar award went to Messrs. Sanders, St. Albans, who staged the handsome Angræcum sesquipedale, with its Comet-like flowers, various cypripediums, some pleasing cymbidiums, and a fine example of Cattleya Enid white, with a purple coloured lip.

Mr. H. T. Pitt, Stamford Hill, who always has one of the interesting exhibits of rare species, on this occasion staged the pretty Eulophia virens, with erect spikes of small greenish flowers; the scarce Maxillaria luteo-alba, Masdevallia triangularis, and the rare Xylobium leontoglossum. The centre of this group was filled with twenty-six examples of the charming little Epidendrum Endresio-Wallisii. A silver Banksian medal was awarded.

Other groups to which similar awards were given included that of Messrs. Stuart Low and Co., in which the central plant was Cattleya Percivaliana var. Little Gem, with five pretty flowers; while on each side cypripediums and dendrobiums were effectively staged; Messrs. Cypher and Sons, Cheltenham, whose varied collection of the leading cypripediums was interspersed with attractive cymbidiums and calanthes; Messrs. Sutton Brothers, Hassocks, Sussex, a new firm, who had a varied exhibit of the popular hybrids, including several plants of Odontoglossum triumphosum, with graceful flowers

A FINE GROUP OF SINGLE EARLY-FLOWERING TULIPS STAGED BY MESSRS. CARTERS.

Digitized by Google

of yellow and brown; Cattleya Clotho, the richly coloured Odontocidium Edwardatum, and well flowered examples of Cypripedium Maudiæ.

Other exhibitors included Messrs. A. J. Keeling and Sons, Bradford, who staged several elegant cypripediums, and Odontoglossum citrinum, with light yellow spotting; Messrs. Black and Flory, Slough, who showed a superb example of Cattleya Mrs. Robert Paterson, as well as several distinct cypripediums; Mr. Harry Dixon, Wandsworth Common, who exhibited several pretty odontiodas and Cymbidium Cravenianum, the latter with spikes of a peculiar bronze-rose colour; Mr. J. J. Bolton, Claygate, Surrey, whose Odontoglossum Exworth with a spike of thirteen flowers of chocolate red colour, and Odontoglossum Garnet, with eleven flowers of red-brown, both received appreciation.

Mention may also be made of several beautiful cymbidium hybrids shown by Sir George Holford, representing the latest advances made in the various sections of this popular genus; and of the elegant Brasso-Cattleya Gatton Lily, from the garden of Sir Jeremiah Colman, Bt.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

MUTISIA CLEMATIS.—This is one of the most ornamental of our greenhouse climbers. The foliage is of a pleasant light green with a woolly grey covering which renders it very attractive. The long pendulous flower heads are highly decorative, with from nine to ten delicate pinky red rays which are slightly recurved, showing the staminal flowers closely set in the centre. This is a vigorous grower and readily adapted to greenhouse culture. Shown by Lieutenant-Colonel Messel (gardener, J. Comber), Handcross.

LINDENBERGIA GRANDIFLORA.—Another decorative greenhouse subject, with dainty yellow flowers borne in a long loose terminal leafy spike. The foliage is of a light-toned green, soft and hairy, characteristic of the scrophulariaceæ, of which this is a member. It makes quite a valuable winter-blooming plant. Shown by the Director, Cambridge Botanic Garden.

CYRTANTHUS LUTESCENS.—This species is a representative of a little-known family of tender bulbs from South Africa. Some require greenhouse culture in this country, while others, again, may be planted out in summer. All are characterised by long pendulous or semi-erect flowers borne in an umbel. In this particular species the flowers are of a bright yellow with a strong honey scent. Very decorative when in a pot. Foliage strap-shaped. Shown by Mrs. Frank Platt-Barlow, Hans Place, S.W.

RHODODENDRON PINK DELIGHT.—A fine arboreum hybrid raised by Messrs. Gill of Falmouth. The wide-open white flowers tinged with a delicate pink round the margin of the petals, which are pleasantly crinkled and frilled, are borne in well formed and closely set trusses which sit tight on the foliage. The leaves are dark green in colour and set off the truss to advantage. It has every appearance of becoming a popular hybrid. Shown by Messrs. Gill and Sons, Falmouth.

ORCHIDS.

CATTLEYA MINNEHAHA (C. Trianæ × C. Lady Rowena).—Six plants of this beautiful hybrid were exhibited by Baron Bruno Schröder, Englefield Green, Surrey, all of which bore large flowers of fine formation, pure white, except for some lemon yellow colour in the throat of the labellum. An award of merit was given to the finest example.

CYMBIDIUM FLAMINGO VAR. WHITE WINGS (Alexanderi × Merlin).—A very beautiful hybrid with an erect spike of six large flowers, white, with a median line and some markings of light crimson colour on the labellum. Shown by Lieutenant-Colonel Sir George Holford, Westonbirt, Tetbury, Glos. Award of merit.

CYMBIDIUM MIRANDA VAR. LEMON QUEEN (Lowio-grandiflorum × Alexanderi).—A delicately coloured variety with an arching spike of fourteen large flowers of clear lemon yellow in the sepals and petals, the labellum white, spotted with red. Shown by Lieutenant-Colonel Sir George Holford. Award of merit.

BRASSO-CATTLEYA WARNHAM BEAUTY (B.-C. Digbyano-Mossiæ × C. Tityus).—This showy hybrid bore a couple of large flowers of a uniform rosy mauve colour, the broadly developed labellum having a rich purple front lobe, crisped at the margin, and with yellow in the throat. Shown by Mr. C. J. Lucas, Warnham Court, Horsham. Award of merit.

ODONTOGLOSSUM GATTON PRINCE.—A fine result in the production of rich coloration. The spike bore three flowers, in which the roundly formed segments of crimson-red have a white marginal zone. Shown by Sir Jeremiah Colman, Bt., Gatton Park, Surrey. Award of merit.

ODONTOGLOSSUM ALVARA (Ithone × Clovis).—One of the best of recent results, and one which promises to be even finer when the plant reaches maturity. The seedling bore a spike of four unusually large flowers of deep crimson colour, having a pretty sheen, the segments margined with white, finely toothed, and the labellum bearing a prominent spiny crest of yellow colour. Shown by Messrs. Charlesworth and Co., Haywards Heath. Award of merit.

ODONTONIA NESTA (Odontonia Gladys × Odontoglossum St. George).—A promising seedling, not fully developed, but with a couple of large flowers displaying much of the Miltonia vexillaria formation; the segments blotched with crimson on a rose ground, the expansive labellum marked with similar colour, and with a yellow crest at the base. Shown by Messrs. Charlesworth and Co., Haywards Heath. Award of merit.

HOW TO SPRAY

SIMPLE though the task may be to those who have had years of experience, there is much need for the exercise of care both in the preparation and application of spray fluids. Observation shows that even though proprietary brands of chemical mixtures only require dilution with water, the efficiency of many excellent sprays is frequently reduced through lack of understanding.

There may be justification in the case of extensive fruit farms or potato plantations of many acres for adopting the rule that chemicals shall be blended on the premises, but in private gardens there can be no question that the safest and most economical course is to use a well known firm's spray fluids or pastes, and to follow the manufacturer's directions with care. Many substances of which the most serviceable sprays are composed are only partially soluble, and a very important point is that the insoluble particles shall be kept in suspension. The practice of filling the container of a spraying machine with water and then tipping in the requisite quantity of chemical mixture is by no means the best method of securing proper suspension of insoluble particles throughout the whole volume of water. The correct method is to mix the spray in an open-topped vessel, stirring vigorously while the chemicals are slowly added. Wooden tubs or wooden pails are better than metal vessels; they are, indeed, essential in the case of caustic soda washes, copper solutions and a few others, unless the alternative earthenware can be used, and since it is necessary in some cases to avoid metal, it is well to use wooden tubs for all. Hot water is better than cold, but perhaps even more important is the character of the water. Rain-water is unquestionably the best, as in the case of ordinary water the metallic ingredients may have a certain influence upon the character of the spray.

Whatever may be the nature of the spray or the subject to be sprayed, windy weather must be avoided for the operation. In the case of poisonous and caustic sprays this is of serious importance by reason of the risk attached to surrounding crops and to the operator. Even a light breeze is sufficient to divert the course of a fine vapour-like spray, and it is advisable to keep to the windward when there is any movement in the air.

When using caustic soda the operator should wear thick leather or rubber gloves, and old clothing or an overall. In such cases also it is advisable to cover the face and neck with a coating of vaseline.

Whenever the selection of a spraying machine is brought under consideration the need for a powerful pump is very properly urged. Ordinary intelligence will surely make clear the fact that to hold the jet close up to branches or trunks of trees while fluid is forced out at high pressure simply means that the spray will beat against the tree and rebound, probably coming to rest on the soil several feet distant; that is usually a sheer waste of chemicals. The real object of spraying is to coat every part of the surface of the trunk, branches and twigs with the thinnest possible film of the fluid. A powerful pump is necessary to drive the fluid with sufficient force through a very fine nozzle in order to break up the spray into a fine mist. The adhesion of the spray fluid is facilitated by the mixing of a certain amount of glutinous matter with the essential chemicals. This is an important point upon which all the best manufacturers of spray fluids focus adequate attention. When an operator realises the importance of these few points he will find it quite a simple matter to hold his lance at a distance and an angle that ensures the spray coming to rest just where he wants it; furthermore, it will become apparent that the best work can only be accomplished when the lance is kept

Digitized by Google

slowly moving, never still, because if too much spray falls on one place it will begin to run to the lowest point. One may demonstrate this in the following manner: Dissolve some ordinary whiting and with a fine nozzle on a spraying machine spray the glass of a greenhouse roof or a tilted garden frame. One fleeting movement of the lance with pump in action will deposit a good coating of whitewash over the glass; but stand still and spray for half a minute on the same panes of glass and the liquid will start to run, and will continue to run to the eaves until, except for a few streaks of white, the glass is left almost clear, and the bulk of the whiting will have dripped off the eaves of the roof or the bottom edge of the light. One may see the effect still more plainly by driving a whitened spray on to a sheet of rough brown paper hung vertically. If one gets at the right distance and adopts the right movement of both lance and pump, the paper may be completely and evenly whitened without appreciably discolouring grass over which the paper hangs, but if the nozzle is held too close or too still the paper will be only streaked and mottled with white, while the lawn beneath is thickly smothered with whitewash.

So far as application is concerned, the greatest lesson is learned when the folly is realised of "putting plenty on" with the idea that thus assurance is made doubly sure.

In warning the operator against allowing forcible contact of the spray against the tree, the remark was made that this is "usually" a sheer waste of chemicals; the possibility of exception is thereby implied, and such exception arises when the particular object of spraying is dislodgment of woolly aphis, or American blight as it is sometimes called. The aphides barricade themselves behind their ramparts of white woolly substance, and when using petroleum emulsion or other contact sprays it is well to use the needle jet instead of the diffusing nozzle. Drive the single jet into all the cracks and crevices in the bark with all the force possible, for thus the woolly coating may be dislodged and the spray be brought into contact with the aphides.

In regard to spraying machines, it may be truthfully said that, like motors and gramophones, any machine to-day which bears a well known name is a good machine—it must be to hold its own on the market. Each of the high-class makes possesses some characteristic which secures the special favour of some users. It is a moot point whether one make is superior to all in any vital point. Machines that are got up for cheapness are not cheap, but to be efficient a machine should be made of metal suitable for containing all the chemical mixtures used for spraying. It should, if of larger than knapsack size, contain some sort of agitator to keep the ingredients of the spray in suspension, and should be fitted with an adjustable lance which can be made sufficiently long to reach the top of a reasonably tall pyramid tree or through from one side of a tree to another.

Interchangeable nozzles, sound washers and a powerful pump are the primary essentials of a good machine, and the final imperative need is that the sprayer should invariably be thoroughly cleaned immediately after use and before sediments can dry or corrosion commence.

A. J. MACSELF.

CORRESPONDENCE

VIBURNUM MACROCEPHALUM.

SIR,—I am delighted to see, in THE GARDEN of February 6th, Mr. Cox's praise of my favourite Viburnum macrocephalum, which always seems to me to be so seldom noticed. I am only surprised that he does not consider it hardy. I admired it at a Temple Show in 1902, and purchased two plants from Messrs. Russell. I planted them among shrubs in rather a low part of the garden; they grew, but did not attempt to flower. I moved them to a more sunny spot, but had no result. Then I saw a remark in a horticultural paper (I believe THE GARDEN) that V. macrocephalum did best on a wall. I moved one plant to a low wall facing south-west: the effect was magical—it was soon covered with flowers, principally in June, but often giving a second crop later in the summer. My second plant was moved to a higher wall with the same aspect below a terrace, and it flowers equally well, and, so far, they have not suffered from any winter we have had. Here in north Nottinghamshire we often have low temperatures, and do not consider that tender shrubs stand very well with us. No olearias except Haastii will grow with us, and that only on the terrace; shrubby veronicas, except Traversii, will not stand the winter. On the other hand, Ceanothus Gloire de Versailles does very well as a bush, without a wall. Viburnum fragrans grows and flowers in November and December. I wish it would wait till February as it is supposed to do—one can hardly enjoy its flowers in December. V. Carlesii does pretty well. Of course, I do not know where Mr. Cox lives, but as he considers V. macrocephalum, which does well here, tender, I am tempted to try some of the newer shrubs which he recommends, especially Ptagianthus Lyallii, which he places among the dozen best shrubs.—A. MELLISH, *North Notts.*

ROSE ZEPHIRINE DROUHIN.

SIR,—I was much interested in your article in THE GARDEN for February 6th on plants which have fallen out of popularity. May I draw your attention to the old pillar rose, Zéphirine Drouhin, which is seldom mentioned and less often grown. I have several good plants on arches, and a long fence entirely given up to it. In my opinion none of the new climbers can touch it, for it seems to have every virtue. In fact, a friend on seeing it and hearing its merits, expressed surprise that any other rose was ever grown! It is the first to flower and the last. I have picked beautiful blooms in December. Its constitution is very robust, and it can be increased freely from cuttings. Its chief virtue, however, is its wonderful colouring—a clear rose pink which never alters, either in bud, full blown, or however late in the season.

For about seven months in the year it flowers unceasingly, and throws up great bunches of buds which require drastic thinning to ensure the best results. The only treatment it requires is to cut out the old wood in the autumn and tie down the enormous shoots it has thrown up during the summer.

Zéphirine Drouhin is heavily scented and, I may mention, is thornless.

Everyone who sees this rose in flower expresses the greatest admiration, but never seems to have heard its name before.—(Mrs.) E. H. PALMER, *Naburn Hall, York.*

PIERIS IN SCOTLAND.

SIR,—I have read the interesting correspondence under the above heading and do not remember having seen any reference to what we here consider the most important question *re* the hardiness of these shrubs. I refer to the loss of the bloom buds by frost. We find P. japonica and P. formosa absolutely hardy, but their prospects of flowering always depend on the severity of the winter, since the buds, formed in autumn, are apt to be destroyed. These buds will stand a good deal, but 22° of frost on several consecutive nights last December cleared every bud off a fine big bush of P. formosa and practically all those of P. japonica save those, curiously enough, on the side facing due north. The foliage in both cases was quite unharmed.—A. T JOHNSON, *North Wales.*

FLOWERS IN A CANADIAN GARDEN.

SIR,—I thought your readers might be interested to know that in this far distant part of Canada, I found the following plants flowering pretty well in my garden on December 27th last year: Helleborus, salvias, polyanthus, alonsoa, Ceanothus Gloire de Versailles, gladioli, Shasta daisies, violets, antirrhinums, primulas, calceolaria, Romneya Coulteri, mesembryanthemums, carnations, dianthus, heaths, hypericums, fuchsias, auriculas, geraniums, roses, verbenas, cerastium, wallflowers, penistemons and chrysanthemums.

It has been an exceptionally fine autumn and winter with us, and two weeks ago I picked a basket of ripe raspberries. Also yesterday I was talking to a gardening friend, and he said he had twenty species of rock plants in flower.—F. B. PEMBERTON, *Victoria, British Columbia.*

RED SAGE.

SIR,—In reference to an article in THE GARDEN of January 2nd on the question of red sage, I consider it very misleading for Victoria Slade to quote bergamot, monarda and red sage to be one and the same thing. The Bergamot orange or Mellarosa is a pear-shaped fruit of a smooth pale golden colour from which an essence is distilled and known as bergamot scent, while Monarda Fistulosa, being of a different family altogether, is only associated by its perfume, being similar to that of bergamot, red sage or Salvia officinalis, belong to a family entirely different from that of bergamot or monarda.—A. D. THOMAS, *Herts.*

ROSES UNDER GLASS.

SIR,—In THE GARDEN for January 29th, I was much interested in "Hants" advice and hints in relation to the preparation of the "Rose House," and the pruning, etc., of its occupants for what might be an early crop of blooms. The growing of roses under glass occupied me at one time and my experience may be of interest. When the roses were growing the morning temperatures in the summer varied from 70 degrees to 80 degrees, while the mercury had a most disagreeable and insistent habit of crawling very often up to 120 degrees and 125 degrees by 2 p.m. I had no special love for the later part of it myself, but it was not so with the Queen of Flowers. She appeared to revel in

Digitized by Google

this high temperature and brilliant sunshine and we grew successive crops of bloom for eight or nine months of the year from the same plants. A short rest was then given them, after which they were pruned, the beds given a thorough overhaul, top-dressed with sound fibrous turf, bone meal, blood manure, given a thorough drenching of water, houses closed down and started again. Roses will stand this heavy cropping if well supplied with rich food as buds begin to form and adequate artificial temperatures be maintained, not under 58 degrees at night. In bright sunny weather plants should be sprayed daily in the early part of the day to keep the foliage healthy and prevent red spider. Mildew must be guarded against, draughts being one of the chief causes of its appearance; it is a deadly enemy to the rose under glass, even more so than outside.

Great care should be exercised therefore when ventilating. A double-span house is doubtless the best, with ventilators on both sides, so that in the case of cold or high winds, air may be admitted from the lee side of the house. To those who have the luxury of a rose house, artificially heated, roses out of season are no doubt what would be desired, and, if full advantage is taken, such a house will afford them.

A judicious selection of roses for this class of work is a very important item. It would be interesting to many readers, I am sure, if "Hants" would kindly submit a list of what he considers suitable for the purpose. —WM. GRANT, *Kincardineshire*.

FASCIATION FREAKS

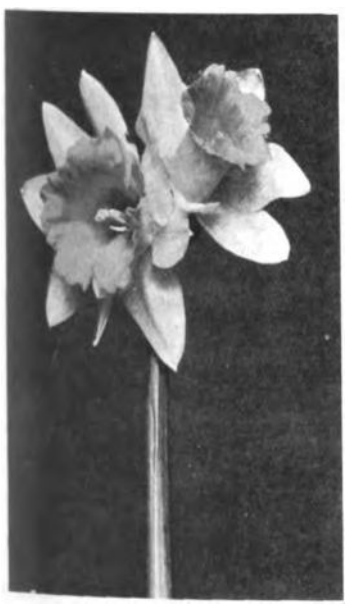
I WOULD ask the reader to visualise some well known members of the cactus family, such as opuntia, phyllocactus or epiphyllum. The external form of these plants strikes the observant eye as something strangely different from that which characterises flowering plants in general. In place of the more or less cylindrical stem which is natural for most plants, the stem in the genera I have mentioned develops as a flattened, jointed, band-like structure, assuming in some cases almost a leaf-like form. In doing so, these plants behave in a way which is perfectly normal to themselves. The flatness is in the constitution of such plants; for them it is the natural state.

And so we grow accustomed to this peculiarity of stem structure in those cases where it occurs regularly as the normal condition. The strangeness of first acquaintance decreases as familiarity with the real nature of the plant increases, and we might be pardoned if we expressed surprise on seeing an opuntia with a cylindrical stem. But should a plant, whose stem is normally cylindrical, like a garden stock, produce a stem or branch flattened into a ribbon-like expansion, we are prone to regard the structure as an unnecessary deviation from the normal, and we may even speak of it in some unfriendly way, using such names as monstrosity, abnormality or malformation to express our feelings in the matter. Technically, this malformation is called "fasciation." The stem or branch affected may be quite round at the base, but becomes more and more flattened upwards, until a band-shaped structure is assumed, due to the great increase in diameter of the axis in one plane. If the rate of growth be equal on both sides, the stem retains a straight direction, but not infrequently the growth on one side is more rapid than on the other, so that a curvature of the fasciated stem results, as is sometimes seen in the ash, producing a structure which has been likened to a shepherd's crook.

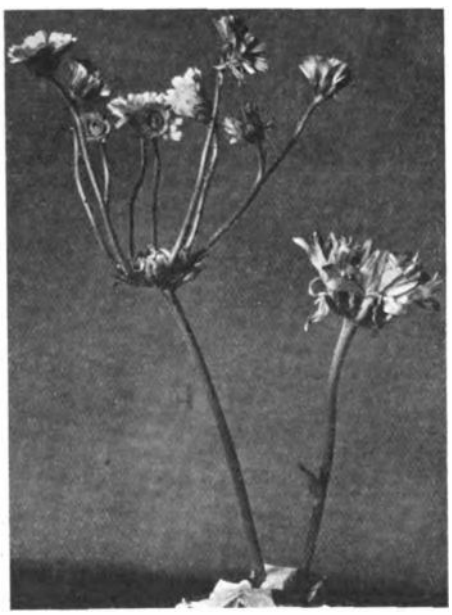
Fasciation is by no means a rare phenomenon. It must be familiar to many readers as occurring in both herbaceous and woody plants. In the former, the abnormality affects, almost invariably, the main stem. A fine example is shown in one of the accompanying illustrations, a remarkable instance of fasciation in the celery-leaved buttercup (Ranunculus sceleratus), a herbaceous type. Here the stem is 10ins. wide, and bears numerous characteristic leaves and hundreds of flowers. The peculiar ridge along the top of the stem is formed of the united centres of about one hundred flowers.

In the case of trees and shrubs, on the other hand, it is much more common to find that the deformity affects only a few of the branches, while the other branches and likewise the main stem, remain quite normal. This condition is not infrequent in the ash and in some conifers, and it has been observed also in barberry, sycamore, elder, prunus, ribes and numerous other woody plants.

As regards the causes of fasciation, we know extremely little; but theories are always interesting, and it may be mentioned that two main views have been advanced. The fusion theory seeks to explain the malformation as the result of union between two or more branches. The fasciation is likely to be all the more pronounced if a large number of buds are formed in close proximity, so that they are liable to become fused together during their growth, owing to the mechanical pressure they will exert upon each other. An alternative view is expressed in the expansion theory, which explains the flattening of the stem or branch as being due to the expansion from the first of a *single* shoot in one plane throughout its period of growth. This theory involves the conception of a number of growth centres at the apex of the shoot, instead of one apical growing region constructed symmetrically as is usual for the normal stem. It is an attractive theory, and it would appear to explain many of the



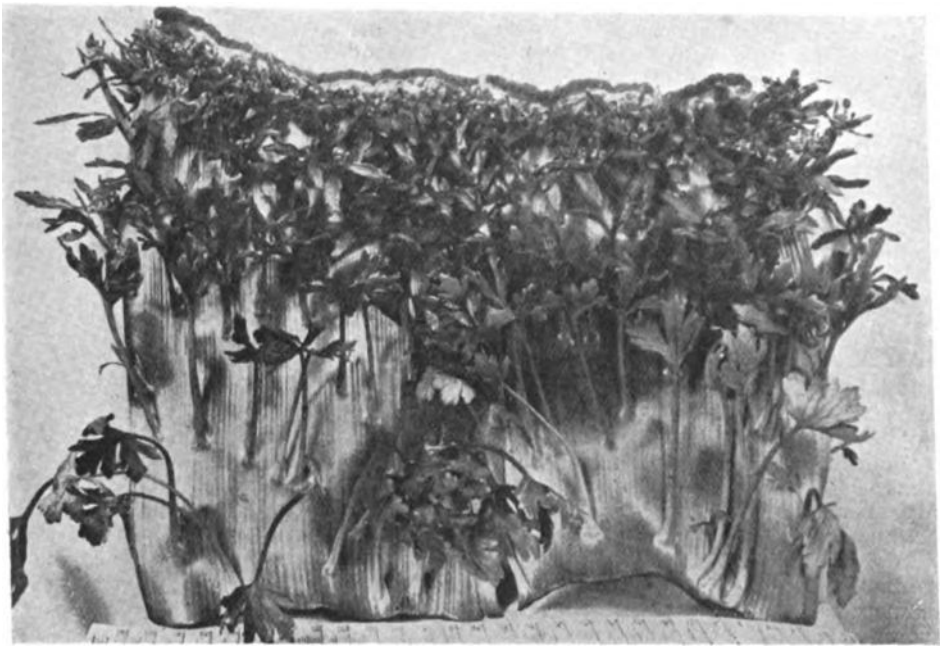
A TWO-FLOWERED DAFFODIL



THE FASCIATED STEM OF A MARIGOLD.

FIVE FLOWERS ON THE ONE STALK.

Digitized by Google



A REMARKABLE BUTTERCUP.

observed facts. For example, along the top of the buttercup stem, there have been many growing points giving rise to flowers, but they have not developed with complete independence, with the result that the flowers remain united laterally in a long row. But, whatever the mechanics of fasciation, we may be certain that some internal factor or factors are involved, and perhaps an unusually plentiful supply of nutriment to the organ affected is the underlying physiological cause. Should the main stem of a young seedling become damaged, it sometimes happens that the lateral shoots, which are developed subsequently, exhibit a fasciated structure. Such behaviour is known in the pea and bean family and is related to the abundant supply of food material in the seed leaves, all of which becomes available for the lateral buds when the terminal shoot is removed. But we cannot say how far this plausible physiological explanation can be applied to those isolated fasciated branches seen in certain trees and shrubs. And again, as every gardener knows, the fasciated condition is the natural inherent state of some common plants in cultivation, such as the old favourite, the cockscomb.

Mention of this plant leads me, in a concluding word or two, to recall the fact that these malformations are found in the flowering region of a plant, as well as in the stem. A case in point is the buttercup shown in the illustration. Another example, which must be a familiar object to many, is the "double-headed" or twin daisy. Those who grow large numbers of tulips may have seen occasional examples of such forking in this plant also. A good specimen is shown on the previous page, where the fasciated flower stem has forked more than once, resulting in the production of several flowers. Twin flowers are not so common in the daffodil, and for this reason the illustration given may be of some interest. J. R. MATTHEWS.

GARDEN TECHNIQUE

Notes on the Technical Side of the Garden and the Cultivation of Plants.

FLOWERS.

MALMAISON CARNATIONS.

THESE plants, although they received much care and attention in the past, are seldom grown nowadays. Yet when well grown they are plants of beauty, both in flower and foliage. Those who still grow malmaisons should now have the young plants—which have been wintered in 4in. pots—transferred into 6in. pots. A good potting compost can be made up of 1 part fibrous loam, ½ part old lime rubble, ½ part clean sea sand, ½ part wood ashes, with charcoal intermixed; and a little ichthemic guano and soot added. The pots should be clean and carefully crocked, then a few beech leaves placed over the crocks to keep the soil from getting down among them. This will ensure perfect drainage, which is very essential in carnation growing. It will depend now on the ball of earth surrounding each plant as to the amount of fresh soil to place in the bottom of the pots, but on no account sink or cover over the surface of the old "ball"; rather aim at leaving it level with the fresh soil, or slightly showing above it after potting is completed. The fresh soil put in the bottom of each pot and around the old "ball" should be firmly packed with the potting stick, then each plant supported with a stake.

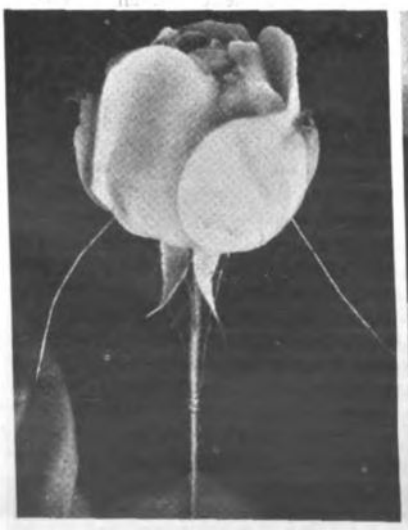
No water should be given to the plants for at least a week or two, according to weather conditions. Malmaison carnations should never be subjected to high artificial temperatures. They do splendidly in an airy, light structure, where only sufficient artificial heat is maintained to expel damp and frost throughout the winter months. Later on in the year, when the sun becomes very powerful, the plants should be slightly shaded, at any rate throughout that part of each day when the sun is shining directly on the glasshouse in which they are growing. At other times, however, they should be allowed all available light. Blinds of some kind, therefore, should be employed, as they can be let down or kept rolled up, according to the intensity of the light.—DAVID ARMSTRONG.

WIRING FLOWERS.

FLOWERS, such as tulips, roses, etc., usually open widely when in a warm room, and then they do not last long. If they are carefully wired, much better results are secured, and this can be done in such a way that it is hardly noticeable. Cut two pieces of florists' wire, each about 6ins. long. Then push these at right angles to one another through the base of the bud, as shown in the illustration. Bend the wires down and twist round the stalk. In this way the petals are held in position and the flower cannot expand and fall to pieces.—S. LEONARD BASTIN.

MASSAGE FOR TULIPS.

WHEN arranging cut tulips it is often found that the stalks of some of the flowers are not inclined just as one would wish. It is quite easy to alter the direction of growth by means of massage. Take the stalk between



HOW TO WIRE A FLOWER.

MASSAGE FOR TULIPS.

Digitized by Google

the thumb and finger and then start rubbing the stalk in the desired direction. Always rub the same way, up towards the flower, and use only gentle pressure. In quite a short while the bearing of the stalk can be moulded in almost any manner that is wished. —S. LEONARD BASTIN.

LOBELIAS IN POTS.

QUITE accidentally the following method of using lobelias to decorate an unheated glasshouse presented itself. The seed was sown in autumn, the intention being to plant out in the border in spring. Pressure of other affairs prevented this, and the plants, quickly growing too tall in the warmth of the glasshouse, began to trail over the sides of the pots. Now the plants are in full bloom, trailing over the sides of the pots and hiding not only the pot they grow in, but also the staging and a good deal of the pots on either side. The effect is very pretty and extremely easy to accomplish—any size pots from 3in. to 6in. seem to do equally well—good soil and *plenty* of water in warm weather. The variety I use is Crystal Palace compacta.—AUSTRAL.

ZINNIAS FOR POTS AND BORDERS.

THE old type of zinnia was much admired by lovers of these flowers, and, indeed, were beautiful when well grown. But the newer types and strains of high merit are much more so. Some amateur cultivators grow the plants and flowers to perfection; others fail entirely. The reason for the failures can, generally, be traced to lack of attention to cultural details while the plants are young. Seeds should be sown in February if the resultant plants are to be flowered in pots, and about mid-March if the plants are to be flowered in the open border. A compost of loam and leaf-soil in equal proportions with a good sprinkling of coarse sand or old lime rubble. Three-parts fill some pots, pans or a box with the compost, firm it moderately, water, allow the soil to dry on the surface a little; sow the seeds thinly, as the seedlings possess big leaves, and cover them ¼in. deep with the same kind of compost. In a greenhouse or a warm frame the seedlings quickly appear, but they should not be disturbed before the two first rough leaves are formed. If they are transplanted too early and before a few fibrous roots are formed, the young plants are seriously checked. Those intended for pot culture should be potted singly in small pots; and those for the outside borders at 4ins. apart in boxes 5ins. deep. Woodlice and slugs will soon spoil good plants if the latter are not protected. I like to keep them on a stage or on raised boards in a frame while they are young. Harden and plant out the first week in June in well manured ground. Heavy soils, enriched with rotted manure and leaf-soil will produce extra fine blooms if slugs are guarded against.—G. G.

GREENHOUSE CYCLAMEN.

MY cyclamen plants flower very satisfactorily with the following treatment: When the plants have finished flowering they are put on a shelf near the glass in the peach house. I give them very little water, but they are never dried off, so to speak.

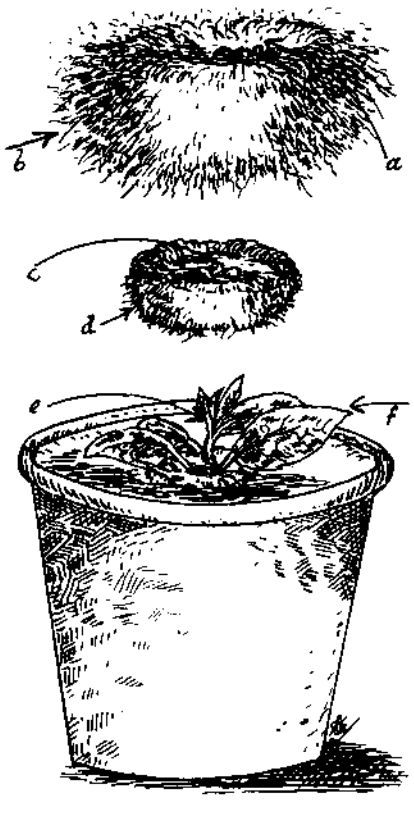
About the first week of June I put them into a cold frame, and they are kept shaded from strong sun. The sash is tilted up so as to admit all the air possible.

The plants are all repotted about the first week of August and are put back into the frame again till about the end of September. I give them a fortnight in the peach house before I take them to the greenhouse, there they go on flowering till the end of April.

They are grown in a compost of 2 parts good loam, 1 part leaf-soil, 1 part decayed moss litter, a sprinkling of sand and a handful or two of crushed bones. Pots are well drained and the plants not too firmly set in the pots.—A. M., *Pitlochry*.

TUBEROUS BEGONIAS: STARTING TUBERS IN POTS.

THESE begonias are invaluable for furnishing the greenhouse and filling the beds in the flower garden. Unlike many kinds of bedding-out plants, a dull rainy summer does not adversely affect the plants and flowers; nor yet a dry season, if the plants are well mulched. The success of the plants depends very much upon the way that the tubers are treated in their early stages of growth. I have seen hundreds of plants, in the boxes in which they were started, 2ft. high in April, the plants being in partial shade in greenhouses. Of course, such specimens rarely prove satisfactory afterwards, either as pot plants or in flower beds. The present is a good time to start rested tubers.



They are in a rough condition, with many dead fibrous roots and old compost adhering to them, as shown in the top sketch. A normal tuber is rounded at the base and hollow at the top. The young growth buds—as I may term them—are near the centre of the cup shown at *a*; these should be carefully preserved undamaged. The rough, loose portion, *b*, should be rubbed off. The cleaned tuber with its crown, *c*, intact, and base and sides, *d*, freed from roots and soil, is now ready for potting or starting in a light compost in a box. The central stem is shown at *e* and the first large leaves at *f* respectively. The pots should be well drained and, till the soil is well permeated with roots, extra care should be taken in applying water. A warm greenhouse is an ideal structure for the plants, and a little shade in very bright weather is beneficial—G. G.

VEGETABLES

SPROUTING SEED POTATOES.

IT is always a very interesting feature of one's reading to note the varied ideas of different writers on the one subject. The suggested idea of so many about the setting up of the seed tubers in boxes will always hold good, but for my own work in trying to get the earliest possible results I can recommend the following system as one which helps very considerably the production of earlier crops. In the growing of first and second earlies, earliness of results is the special feature aimed at, and having for some years been responsible for supplying new vegetables at the earliest time possible in a large public institution, I never knew this plan fail to help in giving the very best results. Provision of boxes suitable for the purpose, according to the quantity of tubers to be planted, is the first necessity. The next provision is an important one, and will be found of the greatest value by all who will take the trouble to adopt it: Place a layer of rotted leaf-mould of a rough sort about an inch thick to cover the box bottom, then as you set up each row of sets fill in between with leaf-mould of a finer degree after passing through a ½in. sieve, pressing it fairly firm up to the level of the eyes. Giving a little extra space between each set is an advantage, and the provision of an extra box or two is a profitable factor when the planting time comes, as it will be found that each set of shoots have formed beautiful rootage into the leaf-mould, which by a little extra care and patience can, with the hand or a small hand-fork, be transferred from the box right into the place of the growing quarters, as each box may be carried as needed to its place of use. If the work of planting is done as it ought to be, a careful look-out kept for likely nights of frost when growth is through the ground, and a little earth drawn up or a little litter or bracken placed over, this system will be found of so much extra value in earlier results, that once tried it will always be practised.—V. H. LUCAS.

THE RAISING OF SUMMER CAULIFLOWERS.

I AM arranging a variety trial of summer cauliflowers during the present season, and I hope to proceed along the same lines, which have always given satisfactory returns in the past. The seed will be sown about the middle of February in clean, well drained boxes, in a mixture of 3 parts loam, 1 part leaf-mould, with sufficient sand added to give porosity. Germination will take place in a temperature of 60 to 65 degrees Fahr. When the seedlings are large enough to handle they will be transferred to boxes of good soil, allowing each plant an all-round distance of 3ins. The plants quickly establish themselves in a medium such as this.

Violent changes of temperature must be avoided or the cauliflowers will suffer a severe check and turn blue in colour. The process can and should be so arranged that the plants will bear setting out in the open garden by the middle of April without feeling the change. Proper development is assured by placing them in rows 2ft. apart, with 1ft. 6ins. between the specimens.

From previous experience I have prepared the ground thoroughly. It has been dug to a depth of 12in. and dressed with farmyard manure at the rate of 1¼ tons to 200 sq. yds. I shall not resort to feeding during the season of growth; it is quite unnecessary after such an application of farmyard manure.

Snowball Erfurt and Early London are three excellent varieties. Of late years, at any rate, the crop has been rather badly attacked in this area by the larvæ of the cabbage root fly, and we have found the corrosive sublimate, or mercuric-chloride, treatment an effective line of attack against the pest. A solution is made by dissolving 1 oz. of the substance in 10 gallons of water. In order to get a solution the corrosive sublimate must first of all be dissolved in

Digitized by Google

1 quart of boiling water and sufficient cold water added to make 10 gallons. Each affected plant should then be watered with a pint of the solution. Commercial corrosive sublimate should always be purchased, because it is obtainable at about 5s. 6d. per pound, which is half the cost of the pure form, and it is equally effective.—GEO. H. COPLEY.

SHALLOTS.

THESE bulbs are valuable for filling up a gap at a time when onions are scarce—when the matured bulbs have been used up and the young ones are only beginning to form. They are valuable because the crop can be cleared off the ground in July, and so free it for other kinds, such as turnips, lettuce, endive, radishes and so on. Some cultivators make a point of planting shallots on certain dates; no real harm will accrue if the soil is in a suitable condition and the weather open. But if these conditions do not obtain early in January it is much wiser to wait until the end of the month before planting. Although shallots will grow in any ordinary soil, they do extremely well in a rich deeply dug loam made firm when in a medium state as regards moisture.

I like to grade the bulbs, selecting the central one or the roundest of each cluster. Having prepared the ground so far as digging and manuring matters are concerned, wait until a fine sunny morning comes, then, quite early, rake the surface over, draw up tiny ridges 1ft. apart and 2ins. high. Leave them so for a few hours, then, when the soil is drier, press in the shallots in the centre of each ridge about 9ins. apart; do not cover with soil. It is a mistake to plant the bulbs too closely as there is not any room for the due spreading out of the leaves and maturing of the bulbs in due course. Allow ample room, and the bulbs will be larger and the crop heavier.—HANTS.

SOWING VEGETABLE SEEDS.

I AM quite sure that hundreds of readers of THE GARDEN find a lot of pleasure in sowing seeds of vegetables, even in cases where they do not feel at all sure that they are doing just the right thing in the right way. There are so many conditions to consider.

Question.—Should seeds be sown in wet soils?

Answer.—No, unless it is unavoidable. If the time of year is passing when seeds should be sown and the ground is rather wet, the best plan is lightly to fork up the surface one day; on the following, early in the morning, rake the surface, then leave the soil so, undisturbed for several hours. If seeds are to be sown in shallow drills, form the latter, scatter some quite dry soil in them, sow the seeds, again scatter dry soil on them and carefully finish the work of covering by drawing on the ordinary soil with the rake. Take care not to tread unduly on the ground, and do not firm it in the ordinary way.

Question.—Should seeds or plants be sown or planted in trenches in naturally wet soils? Peas, runner beans, celery, leeks, these principally.

Answer.—It would be unwise to form trenches other than very shallow ones; the soil would be cold and root action, early in the season, retarded. Only shallow trenches should be made for peas and runner beans in medium light soils; in heavy sow almost on the level. For celery and leeks a shallow trench is superior to a deep one.

Question.—Should the manure be well buried or kept near the seeds or roots of plants?

Answer.—Buried several inches below, so that the roots will penetrate to it.—GEO. GARNER.

CATALOGUES RECEIVED.

Messrs. H. H. Maw and Son, Friarwood Nurseries, Pontefract. List of greenhouse, hardy and bedding plants.

Messrs. Barr and Sons. Bulbs and tubers for winter and spring planting.

Messrs. R. W. Wallace and Co., Limited, Tunbridge Wells. List of bulbs and plants for spring planting, in which is offered a fine collection of lilies.

Messrs. Clarence Elliott, Stevenage. List of seeds of choice alpines and herbaceous plants, in which is outlined the particulars of a children's garden competition.

Messrs. Longstaff and Sons, Chelsfield, Kent. List of gladioli which all growers should procure.

Messrs. Sutton and Sons, Reading. Farmers' Year Book and Graziers' Manual for 1926. Well illustrated.

Messrs. Oliver and Hunter, Moniaive, Dumfriesshire.—List of hardy plants, in which is offered a fine selection of primulas.

Mr. Terry Lee, Stechford, Birmingham.—A list of alpines.

FOREIGN.

Messrs. Johannes Rafer and Son, Copenhagen, Denmark. List of tree seeds, including conifers and flowering shrubs.

Messrs. W. Atlee Burpee Co., Seed Growers, Philadelphia. Seed Annual for 1926. A comprehensive handbook, brimful of information with numerous illustrations. It is a catalogue which all our American readers should have by them.

Messrs. Peter Henderson and Co., New York. A well published handbook entitled "Everything for the Garden in 1926." It runs to 204 pages, and has many coloured and half-tone illustrations. American gardeners will find it useful as a reference book as well as a seed catalogue.

RAISING ASPARAGUS FROM SEED

As seeds are sown in the bed of soil in which the resultant plants are to grow and mature for a number of years, it is essential to success that the beds of soil should be well prepared. In days gone by some cultivators went to extremes in this respect, taking out soil many feet deep and putting in all kinds of material as drainage, even faggots of wood, which, in due course, became a mass of fungus. The plants are more surface than deep rooting, and deep trenching is beneficial; but the best soil should be contained in the top 18ins. or so. Below this depth bury some fresher manure and a small quantity of lime—about 2lb. per square yard. When the plants are older, their roots—some of them—will penetrate to this lower portion of the bed; but for the benefit of the young plants the top soil should be enriched with manure in a more rotted state. Of course, asparagus plants may be raised in a nursery bed, and from it transplanted to their permanent quarters. In such cases the permanent beds should not be prepared till just before they are required. In the southern counties the seeds may be sown late in March; in the northern counties a fortnight or three weeks later. The drills should be 2ins. to 3ins. deep and 15ins. apart. Drop the seeds 3ins. apart, so that the resultant seedlings may be thinned to the required distance apart. Where very clayey soils obtain, it is wise to raise the beds a few inches; but if the soil is naturally light, or the ground on a gentle incline, have the beds level without deep alleys.—CHRISTCHURCH.

DAHLIAS FROM SEEDS AND CUTTINGS

SEEDLING dahlias, well managed, grow very strongly and bear their flowers on strong, upright stems. Where there is unlimited artificial heat, seeds may be sown early in January; but February-raised plants are the strongest, as the seedlings grow without a check where there is a warm greenhouse available. Seeds of all sections may be sown. I strongly recommend those of the single, pompon, cactus and Coltness hybrids. Plants of the latter begin to flower soon after mid-July. The Tom Thumb singles are very dwarf and splendid for bedding-out purposes, or for massing near the front of wide borders of mixed flowers. Loam and leaf-soil in equal quantities with sufficient sand to ensure porosity will form a suitable compost. The pans or boxes should be at least 5ins. deep. Place a thin layer of rotted manure and leaf-soil, mixed, in the bottom, then the compost; level the latter, water, and one hour after sow the seeds about 1in. apart; cover them ¼in. deep. The after-treatment consists of shifting on the resultant seedlings so that there will not be any check to growth and duly hardening in a frame ready for planting out early in June. Old tubers do well started in a mixture of leaf-soil and sand with pure sand round the crowns.

UNWIN'S GOLD MEDAL GLADIOLI

Our 1925 Awards at six of the leading Shows were: Six Gold Medals and One Silver Cup. We offer the very best and most distinct English, American and Dutch Novelties and standard varieties at "*buyable*" prices.

WRITE FOR CATALOGUE (FREE) of all the best Sweet Peas for 1926. Also pedigree vegetables and choicest flower seeds

HENRY ECKFORD, Headquarters for Sweet Peas, Dept. 61 **Wem, Shropshire**

The young shoots should be inserted as cuttings when they possess two joints, being severed with a small heel attached; or, when they have three joints, being severed just below the bottom joint.—G. G.

THE BROAD-LEAVED SEA LAVENDER

COMPARATIVELY few of our good border plants have such a long record of usefulness as the broad-leaved sea lavender, Statice latifolia, which is recorded as having been in cultivation in 1791, and which is still one of the best border flowers, and may be called, without stretching language too far, an indispensable subject for a representative collection of the finest plants of hardy character. A high authority has well said, in speaking of the genus, that "S. latifolia is the best of all," although some of the annual species have perhaps more imposing spikes of inflorescence. Still, they are but annuals, and share the disadvantages for many purposes of their class. Others, again, are only half-hardy; but the hardiness of S. latifolia appears incontestable. While a sandy soil is usually most acceptable to plants of the genus statice, S. latifolia will flourish in ordinary garden loam as well so, that no special preparation of the ground is required beyond having it properly cultivated.

The "book height" of S. latifolia is ordinarily put down at 1ft., but it will frequently exceed this, and will have a really fine appearance when a plant has become established and bears several of its wide-spreading spikes of the small lavender-blue flowers, which, combined with the broad, handsome foliage, will add greatly to the attractions of any border. The leaves, which are of a fine shade of green, are large and broad, and constitute a feature of much beauty.—S. ARNOTT.

Launching an offer of Seeds for trial.

Free and Post Free.

We launch this offer with much the same feeling in which we should approach thin ice—gingerly—because the offer might be thought to somewhere hide the cloven hoof.

But as we are neither asking for money nor making any conditions whatever in offering to send seeds free to anyone who cares to ask for them, it is difficult to see where the hoof could be hidden.

In the hope of getting into touch with a larger number of gardeners than we now have the pleasure of serving, we are sending to all applicants, free and post free, one packet each of three remarkably good vegetable seeds:

BEETROOT—BAKERS' SELECTED GLOBE. A beautifully formed round beet with a conspicuously thin tap root. . . . . .

PARSNIP—GOLIATH. The biggest and best Parsnip that has ever come our way. . .

ONION—MONARCH. The largest growing, best flavoured Onion among those that really keep.

All we ask is that only responsible people will send for the seeds and that they will do their best with them when they get them, because it is only on results that we can hope for the distribution to benefit us.

Where results are good we hope that the grower will be encouraged to learn for himself what Bakers' other seeds are like and so bring grist to our mill.

For our part we can assure all such ladies and gentlemen in advance that the behaviour of the three varieties of seeds we are sending may be taken as a trustworthy guide to the growth and production of all the seed we sell.

Bakers

SEED & FLOWER FARM,

CODSALL.

Nr. Wolverhampton.

To anyone who is diffident about sending for the free seeds we shall be glad to send a copy of our complete Seed Catalogue. In many ways it is an unusual list—more informative than most—certainly more comprehensive and with something about it that might be called the "human touch," as distinct from the cut and dried, soulless sort of production most of us are used to.

2 LO SWEET PEA

THE GARDENER'S BOOKSHELF

TWO NEW BOOKS in the 'Gardening for Amateurs' Series

ARE NOW READY

1. Ornamental Trees for Amateurs

By W. J. BEAN

(*Curator of the Royal Botanic Gardens, Kew*)

2. Herbaceous Borders for Amateurs

By R. V. GIFFARD WOOLLEY, N.D.H. F.L.S.

Each with 15 illustrations and coloured wrapper. 128 pages of text. **5s.** net.

¶ This series now contains E. H. M. Cox's *Rhododendrons* W. J. Bean's *Shrubs*, and the Rev. Joseph Jacob's *Hardy Bulbs*. It is eminently practical and eminently readable—designed for gardeners of not too much leisure but of keen discrimination.

An illustrated prospectus of the series will be sent free on application to the publishers, "Country Life," Ltd., 20, Tavistock Street, Covent Garden, London, W.C.2

ORDER COPIES NOW FROM YOUR BOOKSELLER.

JUST PUBLISHED.

The Scent of Flowers and Leaves

Its purpose and relation to man.

By F. A. HAMPTON.

Cr. 8vo. **6/-** net.

"The author is to be congratulated on the way he presents his facts."—*The Garden.*

"Should find a place and welcome in many bookshelves."—*Evening Standard.*

"A precise and interesting presentation of the principal facts and theories relating to the scent of flowers."—*Scotsman.*

"One of the most interesting chapters is that in which directions are given to gardeners for the laying out and stocking of perfume gardens, by which scented flowers or plants may be grown throughout the year."—*Sunday Times.*

To be Published in February.

The Pruning of Trees and Shrubs

Being a description of the methods practised in the Royal Botanic Gardens.

By W. DALLIMORE.

Assistant, Royal Botanic Gardens, Kew.

Cr. 8vo. Illustrated. **6/-** net.

A most important book both for the professional and for the amateur who has the well being of his trees and shrubs at heart.

DULAU & COMPANY

LIMITED

34, 35, 36, MARGARET STREET

LONDON, W.1

Please mention THE GARDEN *when writing.*

SOME RECENT PUBLICATIONS.

THE success of one or two works lately published by Messrs. Dulau and Co., is already assured. "The Lilies of Eastern Asia," by E. H. Wilson, although only recently published, is already recognised as the standard work on the genus. Apart from its value as a scientific monograph, many gardeners will find the descriptions of these Eastern representatives of lilium and the cultural notes of great help. Their other publication, reviewed three or four weeks ago in these columns, strikes a new vein, dealing as it does with the "Scent of Flowers." It is not a large book nor will it create a big gap in one's pocket, while it will be found most readable and full of interesting facts, gathered together by an author who is well qualified to write on the subject.

It was remarked in this column last week that one or two reecntly published works are likely to interest those more botanically inclined. Botany and horticulture are closely allied and, indeed, are at times inseparable, so it is advisable to have at least a smattering of botanical knowledge. The amateur is often frightened by the formidable scientific tomes, gets cold feet and decides that such are beyond his powers of understanding. For these, an excellent book can be prescribed and that is "Plants and Man," by Professor F. O. Bower, published by Messrs. Macmillan, price 14s. It is an excellent survey of plants in their relation to man and written in the most captivating of literary styles.

For those who are interested in the systematic classification of our flowering plants, I would suggest that they purchase a new work called "The Families of Flowering Plants," Vol. I, Dicotyledons, by J. Hutchinson, published by Messrs. Macmillan at 21s. This work presents no mere arbitrary taxonomic system, but is an attempt to classify our flowering plants on a system based on their probable phylogeny. Many of the modern ideas are embraced which open up a wide field for discussion, and it is a book which merits the close study and attention of all keen botanists and horticulturists.

There is no lack of publications in other branches. Only last week a new book on Sweet Peas, by Mr. C. W. J. Unwin, was reviewed in these columns. Little more need be said concerning it save that it deserves the attention of all lovers of the Queen of Annuals.

There is one book which should most certainly find a place on the shelves of all horticultural libraries, and that is one devoted to the care and maintenance side of the garden. It is an old volume, but a new and enlarged edition has just been published by Messrs. Scott, Greenwood and Son at 15s. net. It is called "Insecticides, Fungicides and Weedkillers." As a thoroughly practical and up-to-date manual on the diseases of plants and their remedies, it calls for close study. It will be found a valuable book to which to refer when difficulties in the way of application of remedies to combat disease crop up. A vast amount of information is contained in its pages, and practically every point relative to the control of disease in garden plants and crops is covered. Besides horticulturists, manufacturing chemists and all those engaged in the growing of crops of all kinds will find it of the utmost service.

A New Book Every Sweet Pea Grower Should Read:

"SWEET PEAS: THEIR HISTORY, DEVELOPMENT AND CULTURE."

Price 5/- net. *(Postage 5d.)*

By CHAS. W. J. UNWIN.

THIS new book will be enjoyed by all who love or grow Sweet Peas, indeed by all flower lovers. Every phase of up-to-date culture for all purposes or objects is treated in detail. It is brimful of interest and practical assistance from cover to cover, and admirably illustrated with photographs, a coloured plate and sketches, while its scope embraces all aspects in detail which are likely to help any and every amateur grower and exhibitor.

WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-

are making a great *noise* in the world. Rich, harmonious colours, mixed, 12/- doz. clumps. Lupin List, Herbaceous and Alpine Catalogue free. A necessary warning.—Some firms are selling Lupin Downer's Delight grown from seed. The same remark applies to Lupin Downer's Pink Pearls. It is needless to say these plants are not true.

DOWNER, 2, Drayton Manor Nurseries, Chichester.

The King's Seedsmen
—READING—

1926 PEDIGREE-QUALITY Sutton & Sons Reading

Warning.—In future every packet of "Sutton's Seeds" will bear this seal, and none is genuine without it

ROSES

STANDARDS.

In this form we have still a few interesting varieties such as Persian Yellow, Copper Austrian, and the old Moss, Blanche Moreau. In dwarf form we can still offer the charming old "Painter's" Rose and the species Moyesii and Webbiana. In Penzance Briars we have Anne of Geierstein, Amy Robsart, Lord and Lady Penzance, &c. Our general stock is still good.

George Bunyard & Co., Ltd., The Royal Nurseries, Established 1796. Maidstone.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.

In the *Field*, a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6.

Coloured illustration sent on application if THE GARDEN is mentioned.

Wm. Watson & Sons, Ltd., Nurseries, Killiney, Co. Dublin.

BY APPOINTMENT.

LAWN SAND

To destroy Clover and Weeds in Lawns apply Lawn Sand. Use at the rate of 4 ozs. to the square yard. 1 cwt. is sufficient for a Tennis Lawn.

Price per cwt. **35/-** in kegs carr. paid.

LAWN GUANO

Turf that has to stand hard wear requires a carefully balanced fertilizer. Fisons' Lawn Guano is used by many of the leading Tennis Clubs.

Price per cwt. **33/-** nett. Carr. paid.

WHAT IS IN A NAME?

A FEW pages farther on in this issue of THE GARDEN will be found a note from a reader who complains about the names of most of the modern florist flowers. He says that they lack originality and that they do not help the gardener to distinguish one variety from another. I am entirely in agreement with all that this contributor has to say, so much so that I wish to emphasise one or two of the points he makes, even if I am accused of stealing a little of his thunder.

Presumably all who love a particular plant or plants above their relatives grant that their preference has something that carries it on a higher plane. If the gardener is especially imaginative, he may see in this plant a personality; it may carry itself with a superior grace, it may suit a particular colour sense, or it may be of a shape that fits in with his individual conception of what constitutes the perfect form. At any rate, the gardener considers it to be the first and foremost of its clan; whether he is alone in this predilection, or whether this superiority is universally recognised, does not matter. Now I, and I think most gardeners are like me, at once ask the name of a beautiful plant that I do not recognise. My feelings are worked up, and I am ready and willing to be enthusiastic; consequently, I am all the more disappointed when I am told that it is Somebody's Perfection or the Something Giant. I consider that these names are unworthy and stereotyped, and this feeling is intensified in the case of plants named after individuals, for, as the personality of the person after whom a plant is named is unknown to me, it conveys absolutely nothing. There is a very lovely primula called Mrs. Berkeley that is most inaptly named, for it leaves nothing to the imagination. There are two other primula hybrids, Red Hugh and Aileen Aroon, that, perhaps inexplicably, I consider have been adequately christened, the former because it recalls a definite colour, the latter because it is imaginative and my fancy is given full play.

Our contributor is quite correct when he states that a name has a distinct influence on our first like or dislike for a plant and that it should have either a direct bearing on the plant's appearance, or be sufficiently attractive to be worthy of the plant.

Various raisers have different ideas on the subject. The use of Christian names in a race of dianthus is mentioned in the note; other raisers search blindly and sometimes strike a happy name; at other times they are high-sounding and mean nothing. All these may have their faults, but none is so cold-blooded about the charms of the combination of name and plant as a raiser of hybrid rhododendrons in Cornwall, who chops a chunk off the name of both the plant's parents and joins these chunks together. Apart from the doubtful merit that the expert rhododendron enthusiast may guess the parentage, this system has nothing in its favour. To the ordinary gardener it means an ill-sounding assortment of various letters of the alphabet, and even to the expert it is not of much use, for rhododendron hybrids show enormous variation and two seedlings sent out under the same name may be as different as chalk from cheese.

There is no use glossing over the fact that naming new plants is a most difficult task and that I, for one, would boggle at it; but I do think that more care might be taken to make a name either more distinctive or one which calls attention to a certain specific beauty in a plant.

In order to forestall possible criticism, I might point out that the question of botanical names is entirely different from that of the nomenclature of the florist flower. It is true that many gardeners, from Mr. Robinson downwards, carp at names in "them furrin tongues"; but it must be remembered that botanists are at least consistent in their use of a formula that began many centuries ago, while the colloquial or English name has fallen from the apposite and picturesque usage of the Elizabethan flower lover to the very mundane and poor affair of the present day.

In addition it must be remembered that botanists are an international body with roots in every civilised country and, owing to the constant interchange of ideas and information, a common tongue is not only advisable but a necessity. The horticultural use of species has certainly made it unfortunate that such horrible names as Pentapterygium serpens and Rhododendron porphyroblastum have to be used by the laity in the absence of something more euphonious. At least they mean something to the specialist, who knows that the former comes from *pente* (five) *pterygion* (a small wing) *serpens* (creeping), and that *porphyroblastum* means "with purple buds." On the other hand, Mrs. Somebody and Souvenir de Somebody Else mean nothing; while dozens of Giants and Perfections help neither the expert nor the amateur.

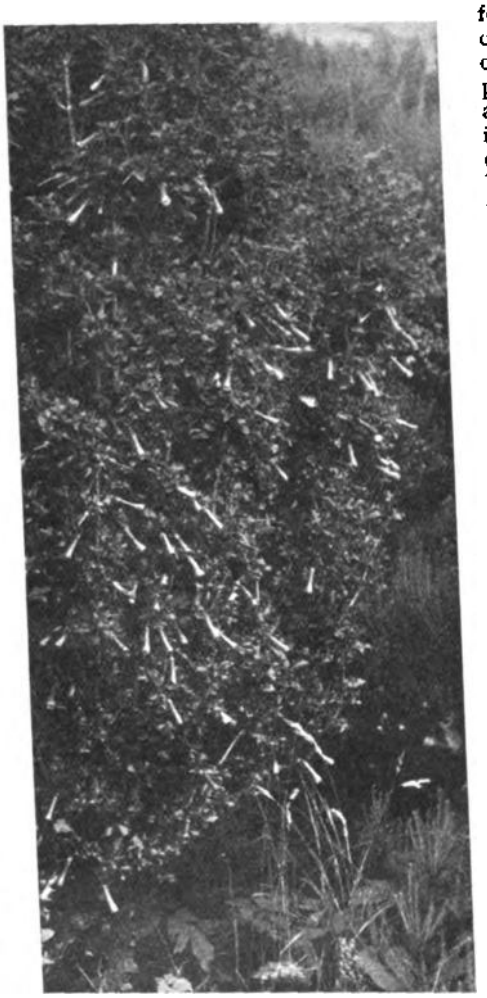
SHRUBS IN WESTERN SCOTLAND

THIS ARTICLE DESCRIBES TREES AND SHRUBS WHICH FLOURISH AT CULZEAN CASTLE. THE WRITER GIVES VALUABLE ADVICE TO ALL WHO GARDEN IN FAVOURED DISTRICTS AND WHO AIM AT A COLLECTION OF DECORATIVE SHRUBS.

IN writing of trees and shrubs in winter one is very much inclined to ignore the deciduous section, because they are not so prominent as the evergreens at this season, and, if the following notes are devoted to the latter, it is because these show up their full beauty and great variety during the dull short days of winter, while the former are uninteresting and leafless. Another point which also requires explanation to the readers who reside south of the Tweed is the fact that the climate of the British Isles is not so much a matter of north and south as is generally supposed, but is in reality a matter of east and west, and that plants from Australia, New Zealand, South America and elsewhere have found congenial quarters, not only in Cornwall and Devon, but so far north as Ross-shire, and in our western districts there is unlimited scope for the planting and successful cultivation of many fine trees and shrubs which as yet have only been attempted in a few isolated places.

The soil along our western seaboard also differs from that of inland districts, clay being rarely met with, and the open friable nature makes it an easy matter to work it to a fair depth and add such helpful ingredients as leaf-mould, peat, sand or manure as may be necessary to encourage a vigorous root action; while the abundant rainfall ensures that the plants never suffer from lack of moisture. Under these favourable conditions, then, it is no wonder to find that delightfully graceful evergreen Azara microphylla reaching a height of 20ft., its neat shining foliage and sweetly scented flowers early in February holding a charm that is not easily expressed. It is not a difficult plant to grow, and, although sometimes recommended for covering a north wall, it makes a splendid specimen when planted in the open and given room to develop naturally, or planted in groups it makes a most effective picture if underplanted with the "Mexican orange," Choisya ternata. This native of Mexico is another favourite evergreen, its tripartite scented foliage making an effective foil to its snow-white trusses of flowers freely produced during April and May, and it may be grown either in sun or shade, although, naturally, it flowers more profusely in an open situation. Choisya ternata shares with the rhododendron family a somewhat rare immunity from attacks by rabbits: perhaps its pungent odour is accountable for this. Both the plants mentioned are easily accommodated with regard to soil; an open loam, to which leaf-mould may be added, suits them admirably.

Another very effective combination of evergreens is made by planting Griselinia littoralis, a native of New Zealand, interplanting with the newer Lonicera nitida, the comparatively large ovate leaves of the former contrasting and enhancing the small foliage and graceful growths of the latter. G. littoralis revels in the sea breezes, and may also be used to form wind breaks and hedges to protect some of the less robust plants. L. nitida is of fairly recent introduction, coming from China, and introduced by Wilson in 1908, but it has proved a splendid acquisition, and will be grown very extensively when better known; it is



DESFONTAINEA SPINOSA WITH LONG CRIMSON AND YELLOW TRUMPETS.

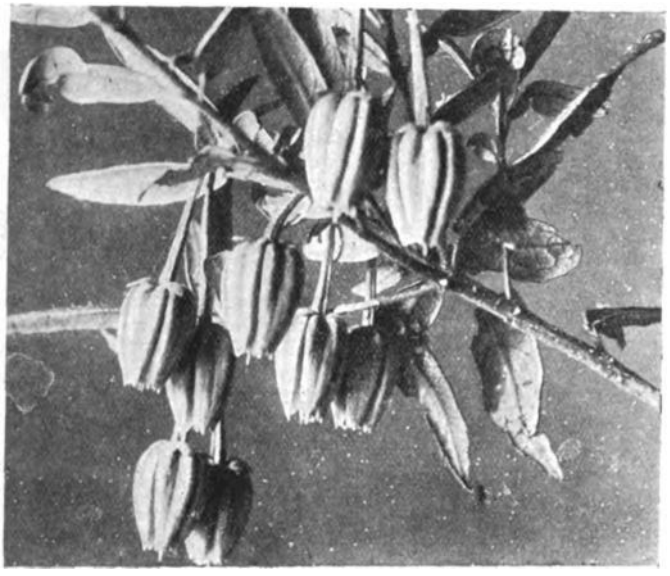
also useful where a neat low hedge is desirable, giving the effect of a dainty small-leaved privet. Quite distinct from the foregoing is Tricuspidaria lanceolata, long known as Crinodendron Hookerianum, its sombre dark green lance-shaped leaves standing out among the paler greens and its erect habit enabling it to show off its drooping blood-red flowers, which are freely opened during June. A partially shaded site is recommended for this gem, but in the west we find that it grows luxuriantly and flowers freely if given an open situation, and in such a position ripe seeds have been produced, which, when sown, came up quickly and made in the course of a few years fine bushy plants; it is also easily increased from cuttings inserted in a cold frame in autumn.

In Desfontainea spinosa we have another native of Chili which has found conditions here to suit its needs. It might easily be passed by the unobservant when not in flower, as a minute-leaved form of green holly, prickles and all; but when its long, tubular, crimson and yellow trumpets are out, few indeed would then pass without closer examination. It grows to a height of 10ft. or more, and its flowers are produced over a long period occasionally so late as November, but its best time is during August and September. The ordinary loam already mentioned suits both these last-mentioned plants admirably, while the addition of leaf-mould is a help with newly planted specimens, but is used sparingly with established plants, as the idea should be to produce short, well ripened shoots in preference to long, soft growths.

Among the olearias there is a number of elegant evergreens of varying shades, all well adapted for garden or pleasure-ground decoration. O. Forsteri makes a handsome specimen nearly 20ft. high, clothed to the ground with its undulated pale green foliage. It is a very late flowering variety, and the flowers, which appear towards the end of October and November, are really of little merit, but as a distinct evergreen it is worthy of a place. The under sides of the leaves are covered with a greyish felt-like substance. O. macrodonta is another handsome member of this family from New Zealand with glaucous green leaves, also felted beneath, and margins dentate or furnished with teeth somewhat resembling a very prickly holly, but soft to the touch. It flowers in June, and its clusters of daisy-like flowers are so freely produced as almost to hide its foliage from view. O. nitida has larger leaves, ovate, and shining green. It forms a large spreading bush 10ft. high and as much as 20ft. in diameter. Its long pendulous flower trusses are freely produced in May and June and are sometimes 12ins. long, composed of numerous greyish white daisies; but the gem of this family is without doubt the beautiful O. semi-dentata, with narrow silvery grey foliage and flowers of a mauve shade, almost as large as the well known Aster Climax, but borne singly on 6in. drooping footstalks. All the olearias are easily grown in our ordinary soil, and need no special admixture to do them well. The family of escallonias are also well represented in the west, and few plants are better adapted to withstand the salt-laden breezes and revel in them than E. macrantha, E. Ingrami and E. exoniensis. The two first mentioned are too well known to need any comment, but where a hedge or wind screen is required, although fully exposed to the sea, E. macrantha is a most indispensable plant to grow. E. exoniensis is probably he

Digitized by Google

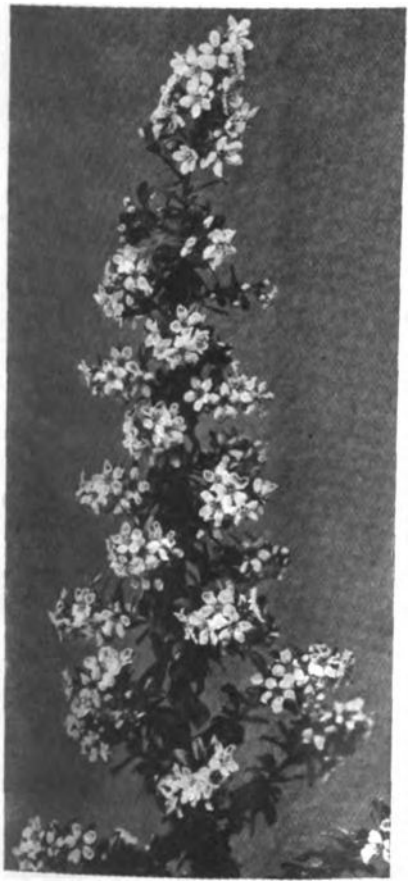
tallest growing member of this family, and grows over 20ft. high; it is also noteworthy because it bears innumerable panicles of white flowers during June and July; but in this family the palm must again be given to E. langleyensis and its hybrid varieties, E. edinensis and E. Donard Seedling. These three have a most graceful form of growth, and the arching growths are clad during June with their different shades of colour, from the deep crimson of E. langleyensis to the rose pink of E. edinensis and the pale blush of E. Donard Seedling, forming a trio that are worthy of a place in every garden.



CRINODENDRON HOOKERI *alias* TRICUSPIDARIA LANCEOLATA.

In Lomatia ferruginea, another native of South America, we have a most distinct evergreen with fern-like foliage which would be worth growing for that feature alone; but when to that is added the clusters of short-stemmed crimson and yellow flowers, it forms a feature, when growing well in July, that is not readily forgotten. This is a very shallow-rooting plant, and its thong-like roots travel just under the surface to a considerable distance from the stem. Some specimens recently noted were over 20ft. high and about 12ft. through, and to see these graceful plants waving in the breeze, showing the dark brown or rust-coloured tomentum on the under sides of the leaves alternately with the dark green upper surface, was a really wonderful experience, and ample reward for the journey. Lomatia ferruginea should always be given a well drained site, so that no superfluous moisture will ever remain around its base, and the top of a natural slope meets this requirement admirably, while the ordinary loamy soil is adequate for its sustenance. Before closing these notes there is one more genus I would recommend where it has not yet been tried, and that is the pittosporums. This family of beautiful evergreens also comes from New Zealand, and in P. tenuifolium (syn. P. Mayi) we have one of the most charming and useful of foliage plants, its neat leaves and twiggy habit make it a most useful adjunct to the decorator's art, and it may be used with good effect along with cut flowers of various kinds. It forms erect, almost columnar, bushes over 20ft. high, and the chocolate-coloured flowers, which are freely produced in April, have a delightful fragrance, especially if visited in the evenings. Seeds are freely produced most seasons, and form a ready means of increasing the stock. They are enclosed in a brown outer covering, which splits open to reveal the black, sticky seeds from which the name of this genus is derived, but they are readily separated for sowing by mixing them with dry sand.

Limited space alone prevents me from describing many more interesting and beautiful plants which are growing in our western districts, and which, I feel sure, only require to be more widely known to be more widely grown. A. T. H.



DONARD SEEDLING, ONE OF THE BEST OF ALL ESCALLONIAS.

OLEARIA SEMI-DENTATA WITH SILVERY-GREY FOLIAGE AND FLOWERS REMINISCENT OF ASTER CLIMAX.

ABOUT WINDOW BOXES

WHETHER the window-box is merely a contrivance of boards, roughly nailed together and given a coat of paint, or is made decorative with more or less expensive tiles (the horrible "virgin-cork" facing of yester-year has vanished), or is not a box at all, but a trough of ornamental terra-cotta, the fact remains that its cubic capacity must be as great as possible. This is especially necessary if the exposure is a very sunny one, for the soil in a shallow box will get bone dry in a very short time unless incessantly watered. Moreover, the box must not sit down flat on the sill, but should have battens fixed underneath to permit free drainage and ventilation. As to the soil itself, it should consist of good fibrous loam with the addition of a little old, dry manure and a dash of sharp sand.

Originality is rarely displayed in the planting of window-boxes; to paraphrase the poet, it is too often "geraniums, geraniums, all the way." Although, most happily, the excruciating mixture of pink Mme. Crousse and scarlet Paul Crampel, once so amazingly popular, is now seldom met with. The value of annuals as window-box plants is not, I think, sufficiently realised; they are not only inexpensive and, in the majority of cases, easy to grow, but they lend themselves to many effective colour-schemes. They are accused, with some truth, no doubt, of being short-lived, but if they are not allowed to ripen seed, they will generally flower until they can be succeeded by dwarf chrysanthemums, grown in a relief box. Careful and regular watering is essential and after a very hot day the plants should be gently sprayed with tepid *soft* water. It is not advisable to sow annuals *in situ* with the exception, perhaps, of large-seeded things, such as nasturtiums); it is far better to raise them in boxes or pots and transfer to their permanent positions when they reach a fair size.

If a very gay window-box is wanted, it may be filled with mixed double French marigolds, orange and yellow, striped and spotted, with dwarf Nasturtium Ladybird, which has scarlet blotches on a yellow ground, as an edging and canary creeper as a "draping" plant in front if one is liked, although I am inclined to think trailers are best eschewed unless the box is a very roomy one on a balcony. A combination of flame-coloured intermediate antirrhinums, such as Fireflame or Orange King, and Nasturtium The Pearl, which shades from cream to yellow, is equally effective, while a pretty red and white scheme can be carried out with the deep scarlet N. King of Tom Thumbs, backed by either white ten-week stock or the giant spiral candytuft which grows to 15ins. high. A similar colour scheme has a scarlet antirrhinum as the principal item with a carpeting of Alyssum maritimum Little Dorrit and Snow Queen. (The ordinary type of this alyssum is apt to be straggling; only a good variety should be used.)

The little annual pink, Dianthus Heddwegii, is a charming window-box plant whether used in separate colours or mixed. D. Salmon Queen, which is single and about 1ft. in height, will go well with Gypsophila elegans and one of the paler blue lobelias and D. H. Vesuvius or Scarlet Queen, tall white China asters and the dark foliaged Nasturtium Empress of India will combine very happily.

Another desirable annual is Phlox Drummondii in all its many delightful colours. A box filled entirely with polychrome phloxes, both the tall (12in.) and the dwarf (6in.) varieties, will look well, but if the colours are limited to deep crimson and pale pink or carmine and white the effect will be daintier. The many different kinds of China asters are all suitable for our special purpose, but none is better than the single aster sinensis, especially in mauve, pink and white; the purples are rather crude and the so-called "scarlets" are perilously near magenta. The three pale colours will harmonise well with each other and with mauve violas as an edging. Zinnias, especially the double ones, make a very gorgeous display. If an edging plant is used with them it should be quiet in tone—creamy white violas, for instance, are suitable.

Of the perennials appropriate for window boxes, nothing need be said concerning the too familiar geraniums, marguerites and calceolarias. Dwarf fuchsias are less hackneyed and have the additional merit of not objecting to a slight amount of shade, although for a really sunless window-box I am afraid one must fall back on ferns and creeping jenny—Lysimachia Nummularia. Pink and white fuchsias, heliotrope of the dark-toned variety and a good pale lavender viola make a pretty combination, as do crimson-purple fuchsias and purple and white double petunias.

Campanula isophylla is a charming plant for the front of a window and the white variety contrasts happily with the vivid scarlet of Salvia Glory of Zurich and as both are sun-worshippers, the same conditions suit them. With the blue Salvia patens either Pyrethrum aurea—Golden Feather—or a deep yellow viola, may be used as a front row plant.

Oxalis floribunda will fill a window-box with its clouds of rosy-pink flowers throughout the whole summer if it has a liberal allowance of sunshine and water. Agathæa cœlestis, the blue daisy, a little half-hardy shrub seldom seen in boxes, but quite suitable for them, will also continue in bloom for many weeks in similar circumstances. Agathæa may have as companion Potentilla Miss Willmott, but is quite effective in a quiet way alone.

R. E. HEAD.

SWEET PEAS OF YESTERDAY

WHEN making my selection of sweet peas for 1926 recently I happened to look back over my notes on varieties, and it occurred to me that a brief article on a few old favourites might be of interest to some of the many readers of THE GARDEN.

The notes referred to were started for the season 1909 and, with the exception of the year 1923, which was a failure, have been continued to date. They comprise a list of the varieties grown each season, the colour of each, from whom they were purchased, and brief notes as to the success with which they were grown.

In the following I will mention some of those which were of outstanding merit but which, for one reason or another, were gradually discarded—though not, I fear, always wisely. Starting with 1909 three sweet peas were especially fine, namely, Evelyn Hemus, Paradise Ivory (Miss Hemus) and Dorothy Eckford. Taking these in order, Evelyn Hemus was grown up to and including the season 1915, and was a beautiful cream-edged pink, very refined and very free flowering. It was displaced by Jean Ireland (Dobbie) in 1916. Paradise Ivory—the name is descriptive of the colour and I have never since seen a sweet pea of this section to equal it, though there are now, of course, many much larger—was grown up to the season 1915, when for some reason or other it germinated badly and, consequently, was omitted. Dorothy Eckford, the old grandiflora white, was disappointing in 1910, and was replaced in 1911 by Althorp White, which, though good, gave very short stems. Apple Bloom Spencer was one of the outstanding sorts in 1910, and, as the name implies, was a very beautiful pale pink, but was superseded in 1911 by an even more beautiful sweet pea, Paradise Apple Blossom. King Edward Spencer (Unwin's stock) was another splendid variety in 1910, and this glorious crimson was grown up to and including the summer of 1916, in which year it was not nearly so good and was badly mixed. Constance Oliver, a glorious deep cream pink, was the only other I need mention in 1910.

Coming to 1911, only two sweet peas not previously mentioned need be noted. The first of these was Mrs. Wilcox, a very large free-flowering white, striped deep red. This was a remarkably showy sweet pea, but was not quite true. The other referred to was Anglian Blue (E. W. King and Co.), a strong-growing and attractive light blue.

Amethyst and Moneymaker were the two noteworthy additions for 1912. The former was a very beautiful and refined deep mauve, the latter a vigorous large-flowered white that was grown until the season of 1915. King Manuel (Stark) should also be included under 1912, a glorious deep maroon which was grown for nine seasons, when it failed and was replaced in 1921 by Warrior, which is included in my selection for 1926.

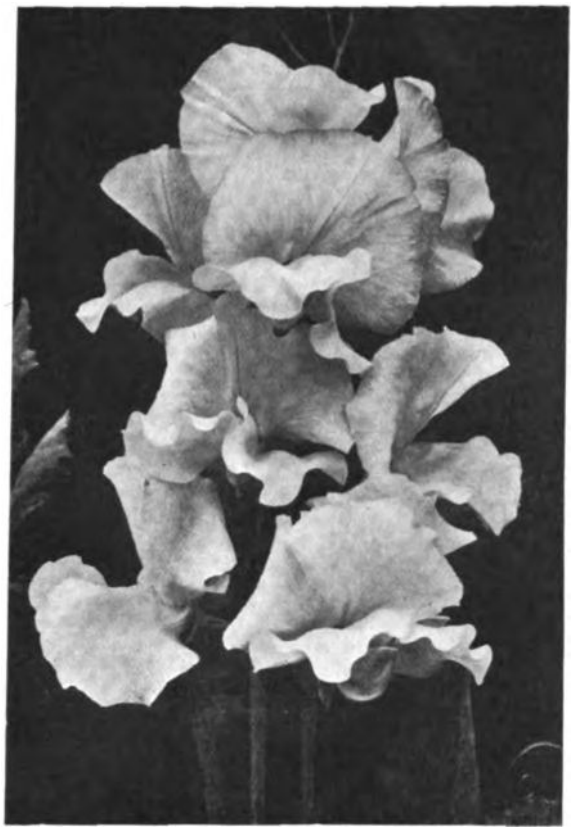
Digitized by Google

Paradise Carmine was probably the most noteworthy of the varieties tried for the first time in 1913, and was a really magnificent sweet pea. The colour was very bright and the flowers were large, but not in any way coarse. Other good sorts grown this year were Prince George (Bolton), rose shaded lilac, a very uncommon and attractive sweet pea; Gladys Burt, a beautiful salmon pink on primrose ground; Senator Spencer, a striking and uncommon variety of grey or pale heliotrope ground colour, striped claret; and, lastly, Veronique, a pretty mauve-coloured form of the old mottled sort Helen Pierce.

Kralissa (Aldersey) was about the best of the 1914 lot, and was a fine bright pink deepening in colour towards the edge, while Dragonfly (Aldersey) was the most uncommon—lavender veined on a cream ground, very refined and beautiful, but, unfortunately, far from true. Hilda (Woodcock), a good orange salmon, also proved a success, as did Dorothy (Bolton), a pale lilac, the principal failing of the last named being shortness of stem. Royal Purple (Dobbie) appeared for the first time in 1915, and is still grown, which speaks well for its merits. It is certainly one of the most distinct and satisfactory garden varieties even now. Wenvoe Castle (Bolton) was very fine at this season, and was a beautiful rosy mauve shaded blue. It was very free flowering, but with us gave no "fours." Austin Frederick (Woodcock), a lovely long-stemmed pale lavender, was the only other one I need mention for this year.

Jean Ireland, which replaced Evelyn Hemus, and Climax (Woodcock), a very strong-growing bright carmine, were both very fine during the summer of 1916, while other good sorts were Edward Cowdy (Unwin), bright flame colour; Elsie Herbert (Bolton), the popular white-edged rose; Margaret Atlee, a strong-growing cream pink; Progress, a fine deep pink on white ground; and Sincerity, a very beautiful (though with us small flowered) cerise.

With this season we are now approaching the advent of modern varieties, or at least of those that have been so recently discarded as not to need mention, and so I will bring this brief list of old-fashioned sweet peas to a close. Many of those mentioned are, I think, now unobtainable, though Messrs. Ryder and Sons, St. Albans, and Messrs. Sutton and Sons still offer a number, including Paradise Ivory, Evelyn Hemus, King Manuel, Apple Blossom Spencer and Sincerity, and for next season I have obtained a packet of Paradise Ivory for the sake of old times, and hope it will do well. Of course, it must be remembered that, as in other plants, varieties deteriorate after a while, but if good stocks were obtainable I think that many of the old varieties would be worth growing for cutting and garden decoration to-day.



JEAN IRELAND. AN ADVANCE ON OLDER PICOTEE EDGED VARIETIES.

ROYAL PURPLE. OFFERED IN 1915, IS STILL A FAVOURITE.

For freedom of flower and scent many sweet peas relegated to the background nowadays would put some of the modern introductions to shame, not that I would try to decry the merits of beautiful sorts, such as Cecily (my favourite at the present time), Mrs. C. W. J. Unwin, W. J. Unwin, Faerie Queen Improved, Warrior, Mrs. Tom Jones, and the new and very pretty "fancy" Lady Gay introduced last year by Mr. Unwin. I cannot help thinking, and I often hear the same opinion expressed, that the modern exhibition peas with huge frilled flowers and stems like miniature walking-sticks have lost much of the beauty and refinement of some of the old grandiflora and Spencer varieties.

Surely, as in the case of such flowers as the rose and chrysanthemum, it would be worth while for raisers to develop a race of free-flowering, sweetly scented and moderately waved sweet peas which, while not up to exhibition size, would prove invaluable for garden and home decoration. Mr. Unwin, I am glad to say, seems to be working on these lines with the above-mentioned Lady Gay, Faerie Queen Improved and this year's novelty, Twinkles, and Messrs. Dobbie and Co., Limited, Edinburgh, recently introduced a new mauve grandiflora named Dulce. This variety is very pretty and is sweetly scented.

The striped, flaked and flushed section seems to have fallen into disfavour at the moment, and to my mind it is a pity, for many of them were very pretty and uncommon; however, I hope with the advent of Lady Gay and Twinkles interest may be aroused once more in this very decorative class.

The bicolors are another colour section in which little advance has been made, and surely this is a hopeful field

Digitized by Google

for the raiser, with the possibility of colour combinations other than pink and white or cream.

In conclusion, there are a few other old grandiflora sweet peas not mentioned in the foregoing but of which I have affectionate memories, namely, Sybil Eckford, apricot pink; Hon. Mrs. E. Kenyon, buff primrose; Lady Grisel Hamilton, lavender; and Black Knight, maroon. Many, and in all probability the majority, of those who read this article will, I expect, disagree with my criticism of the modern sweet pea, but I hope the notes may give pleasure to some who like to recall to memory some of the favourites of yesterday.

CECIL M. BAILEY.

NOTES OF THE WEEK

FLORISTS' NOMENCLATURE.

ONE may well wonder how any person can ever remember the names allotted to the multifarious varieties of roses, chrysanthemums, pansies, dahlias or, indeed, any florists' flowers. Probably nobody does. The names make up such a monotonous list. The whole purpose of naming is not merely to distinguish, or any name, as equally any number, would serve the object in view. What is wanted is that we should be able to distinguish readily and immediately by virtue of a name, between separate sorts. When varieties of a flower exist in scores, or even hundreds, confusion cannot be avoided unless the individual names are thoroughly dissimilar in character. It is only an extraordinary memory that can recollect which name denotes a certain variety if all varieties carry personal names. Most of us will require to have recourse to a notebook. This use of the personal name is particularly awkward if different subjects are named by merely ringing the changes on the one surname.

It is not the personal name, as such, that is objected to, but the excessive use of it. We have the same ineffectiveness, whatever the names are, if they are all members of a series. Allwoodiis, for example, are inadequately named. It may be good to call one variety Rufus, but when others are called after all the Christian names in the calendar—Mary, Betty, Harold, Dorothy and so on—the varieties may be named, but they are not sufficiently marked off from each other. One forgets if it is Betty that is white or if it is Harold. How different if the white were, say, Paleface, and a deep pink were designated Rosy Dawn. We may get originality with Moseley Perfection, but there can be no merit in the subsequent creation of Porlock Perfection or Paisley Perfection. White Lady is useful, but if White Countess, White Queen, White Slave, White Nun are sure to follow, then the first name loses value. There are too many Gems, Ideals, Stars, Brides, Emblems, Kings and Queens in the nomenclature of the florist. Why go on always insisting on the same trite metaphors? We can have other names for white flowers than those that insist on their resemblance to snow—Snow Queen, Snowdrift, Snowflake, Snowball and Boule de Neige. The same applies to yellows. We have too many references to gold, the sun or the canary bird.

What then, one asks, is a good and sufficient name for any new variety of a flower where the varieties are apt to be numerous? First of all, there must be originality. The name should be by itself, not one of a series. This is a *sine qua non*.

Apart from that, there is, perhaps, only one other essential, whatever else is desirable, and that is that the name should be easy to remember. Out of a catalogue of roses, old and new, one might list names like the following as being memorable, besides being distinctive: Hebe's Lip, The Garland, Rambling Rector, Modesty, Noblesse, Austrian Copper, Village Maid, Colleen, La Tosca, Autumn Tints, Bardou Job, Lady Gay, Janet's Pride, My Sweetheart, Maiden's Blush, York and Lancaster, Independence Day, Crusader, Swiss Boy, Rosa Mundi, Glowworm, Apothecary's Rose, Nova Zembla and Magna Carta. Who that has once heard of the rose Spineless Virgin could hope to forget that name? It is a great excellence in a name if it comes readily to mind. That is what is meant by "memorable quality."

But what is in a name that makes it easy to remember? Here we intrude on very difficult ground, and can give no final answer. Of course, the name which is unique tends to be memorable, like 2LO, Brightest and Best, and Cottager's Scarlet. But that is not always the case. However, there are, apart from this aspect of the question, two types of names that are in the category of being easily memorable. First of all comes the descriptive name. This, at its best, seems to have permanence, and, once learned, cannot be forgotten. The sight of the flower at once recalls the name, the only possible name as it seems. Exemplary in this connection are names such as Cloudy Blue and Flame of Fire. The other type is the bizarre, and, it may be, far-fetched. The very oddness of the name "fixes" it, as in the case of Spineless Virgin. One has no quarrel with such a type of name, so long as it is not hopelessly grotesque; but as the gardening fraternity includes all sorts of people, a name obviously should not be too difficult. A simple designation is less apt than the far-fetched or the recondite to go forth into the way of folk adaptation, and, if we take some manner of simplicity as recommendable, we shall avoid the possibility of mutilations like "Glory to John" (Gloire de Dijon) or "Thursday Morning" (Desdemona).

A name may at times have another merit, not merely essential and utilitarian, but only desirable. It is the merit of being a nice name, having something pretty about it in sound or symbolism. Our ancestors achieved poetry in the names they gave to their garden flowers and the flowers of the field. They have handed down to us such haunting names as Sweet William, love-in-a-mist, Star of Bethlehem, snow-in-summer, monk's hood, ragged robin, love-lies-bleeding, traveller's joy, lady's smock, London pride, sea holly, forget-me-not, lily of the valley and Solomon's seal. But the imagination that inspired names like these is almost non-existent to-day. One may find it to some extent among the daffodil raisers, who do, more than others, seem to make an attempt at times to fit a beautiful flower with a beautiful name.

The flower by any other name may smell as sweet and look as fair, says the poet; but he is wrong. The very name, to any impressionable person, is too much part of the flower to be completely negligible. Pass round your carnation beds and there will be no irritation as you linger over the charms of Sweet Anne Page. Had the same variety been labelled Mrs. Patrick Murphy, it is possible you might have had less satisfaction in lingering. "Souvenir de R. B. Ferguson is a great rose which the raiser did not popularise at christening. The Land of Cakes was surely capable of a sweeter sounding name than this curious mixture of Scotch and French." This passage is quoted from the catalogue of a firm of rose growers. As a class, florists hardly seem to understand the importance of good nomenclature. They cannot convince themselves that an evil name, completely lacking in originality, discounts sales. It is freely admitted that a good name will not sell an indifferent flower, nor will an evil name damn everlastingly a flower of quality. None the less, it is certain that the name does have some effect, one way or the other.—J. MACGREGOR, *Cumbernauld*.

SHRUBBY VERONICAS AND FROST.

THE recent sharp spell has decided the hardiness or otherwise of many plants. Shrubby veronicas are favourite plants with me, and I am sorry to find so many of my collection have proved unsuitable. The hardiest of all are Traversii and canterburyensis. These are the only two absolutely unscathed. Salicifolia is injured, but will lose little wood. The same may be said of Hulkeana. A dark blue hybrid has come through fairly well, as also has Dieffenbachii. Total casualties are Lewisii, chathamica, Barkeri, parviflora and several unnamed species used commonly as hedge plants in the west of England.

This is a rather discouraging account, as my soil is light in nature, and the plants were, in many cases, in somewhat sheltered positions. I acknowledge that in most cases the plants were small, but veronicas generally withstood sharp winters better in my Surrey garden, which was stiff clay.—E. BROWN, *Sittingbourne, Kent*.

THE HADLEY FEDGE.

FOR several years I have been watching with tremendous interest the growth of what I think a most excellent and original fence or hedge. Strictly speaking it is neither quite fence nor entirely hedge, but a sort of bigeneric hybrid between the two. Hence the hybrid name—"Fedge."

I have never seen a fedge anywhere else, nor heard of one and as it combines the virtues of both its parents and escapes most of their faults, it would seem to be an invention worth putting on record.

The faults of pure bred hedges and fences are pretty obvious. The wooden fence as a boundary, especially between garden and public road, asks to be climbed. It is so firm and solid that it might have been built for no other purpose than to be climbed. No boy, moreover, can pass it without rattling a stick along its ribs. Spiked iron, corrugated iron and barbed wire fences should, of course, be destroyed at sight. Split chestnut fences are good up to a point, being durable and comparatively inexpensive. But they are too draughty and transparent to make a desirable rampart between garden and road. A hedge may be opaque and snug, if you keep it constantly and efficiently shingled, but all hedges tend to go into holes at the bottom and no hedge is entirely dog-proof.

The fedge takes a couple or three years to come to perfection and then it is well-nigh perfect. It is durable—lasting many years—it is practically unclimbable, it makes a perfect evergreen blind and it needs far less coiffing than any hedge I know. Just

Digitized by Google

a trim over now and again. Moreover, it flourishes equally well in the open and under the shade of trees. Of how many hedges can you say that? Dogs cannot come through it, nor Peeping Toms see through it, and it is reasonably cheap.

You want to know what a fedge is and how to make it? I will tell you, though when you know, it is too utterly silly and simple. Anyone could have thought of it, though apparently nobody did, or if they did the idea has never been made known.

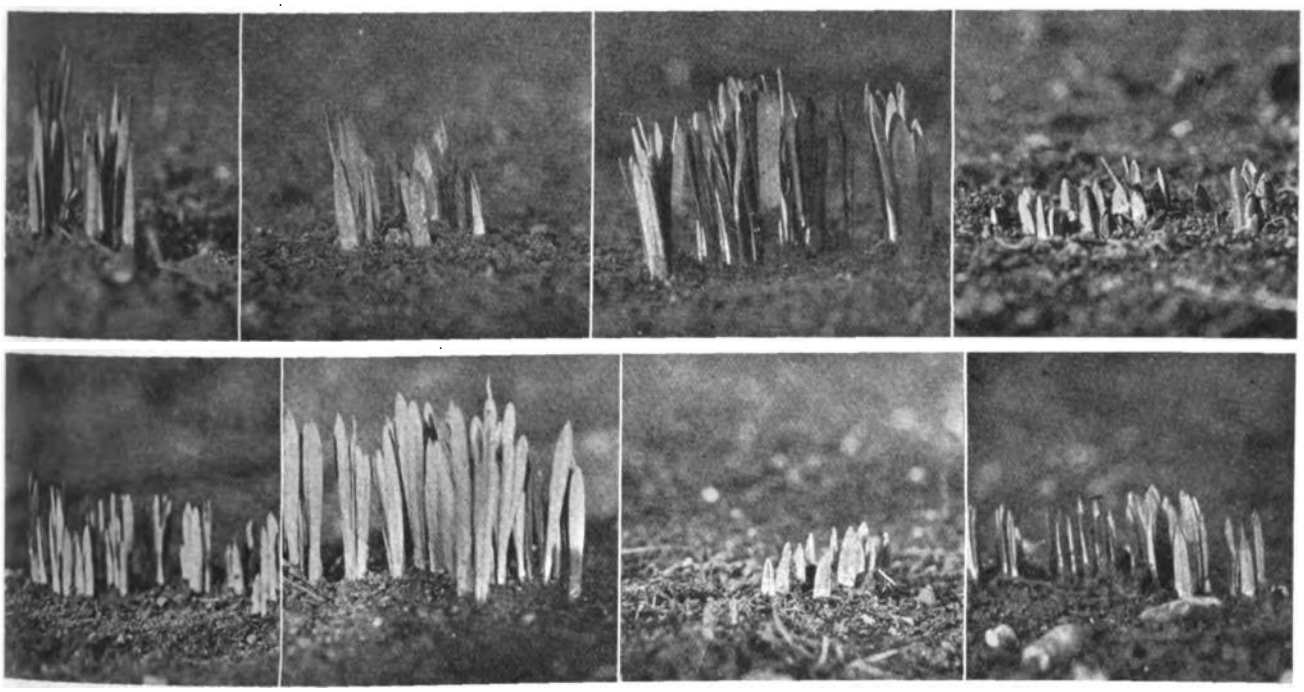
A fedge is nothing but a split chestnut fence planted with ivy. You erect your split chestnut fence and if you do not like the pointed tops, you can saw them off. You buy the fencing ready made and can get it whatever height you like. In erecting it, do not strain the wires too tightly. If you leave it slightly saggy and loose it will be all the more difficult to climb. A split chestnut fence is about the most lasting form of fence known and no dog can go through it. Having erected it, you plant along its base, in a prepared trench of decent soil, and about 9ins. to 12ins. apart, young plants of ivy—large-leaved variety for choice. After that all you need do is to give the ivy a leg-up with a tie here and there, as it grows, and ivy grows most encouragingly fast. After the first few months the ivy will begin to cling to the fence with its own toes and will look after itself.

Within a couple of years, with good culture and any luck at all, you should have a fully fledged fedge. I do not claim that the idea of the fedge is an entirely new one, but certainly it is not known as it should be. I have seen countless miles of privet, laurel, barbed wire and what-not up and down the country, but the Hadley Fedge is the one and only fedge I have ever come across. And now I have given away the locality where the fedge is to be seen. Well, I comfort myself with the thought that the crowds of GARDEN readers who make pilgrimage next week to gaze upon the Hadley Fedge will be perfectly orderly crowds and that even were they not, the owner, secure behind the splendid rampart of his fedge, would be quite unaware of their presence!—CLARENCE ELLIOTT, *Stevenage.*

WEATHER OBSERVATIONS FROM A DAFFODIL CLUMP.

THE enclosed photographs may be of interest to many of your readers as throwing light on the extent to which spring is retarded by such severe weather as we have had this winter? The illustrations are of the same daffodil clump, taken on February 1st for twelve years past; and they show—as do others of the photographic records of vegetation taken in connection with my meteorological station—that despite the severity of the cold, there have been various later springs recently. The reason, as shown by various records, appears to be that vegetation's advance does not so much depend on mean temperature as the excess of temperature above a given level. Were the temperature, for example, to remain for a week at 40 degrees, no growth might be made. But were it to dip to 35 degrees by night and rise to 45 degrees by day, although the mean temperature would be similar, plant growth would be appreciable. For the growth achieved by a plant in the warmer hours is, of course, only arrested, and not nullified when cold arrives. —JOHN H. WILLIS.

[We have not published all the photographs sent in by our correspondent, as in the case of the years 1921, 1923 and 1925 the growth was practically the same and one illustration suffices, while in 1917, there was no growth, the ground being snow covered. Again, in 1918 and 1919, the growth was almost equal, and the one photograph indicates the height reached in both years.—ED.]



Top: 1914 1916 1918, 1919 1920
Bottom: 1922 1924 1921, 1923, 1925 1926

CAMELLIA SASANQUA.

FOR many years we grew large bushes of this shrub in a cool house, from which frost was barely excluded. Planted out in a border of rather light loam, occasionally top-dressed with horse droppings, they grew vigorously enough and attained a height of 7ft. to 8ft. The branches are always slender, often drooping and the leaves smaller than those of Camellia japonica. Continually breaking out into new growth, the plant is never at rest, yet under glass it flowers very freely. The comparatively small flowers 1in. to 2ins. in diameter, single and semi-double, vary in different varieties from white to rose pink. Under cool house treatment they are produced over a rather long period, from November to the end of January. During the war the houses were required for other purposes, and it was decided to plant some, at least, outside. Placed in a sheltered and somewhat shady corner, they proved a disappointment, making very late growth and refusing to flower. Eventually they were crippled by the severe frost in the winter of 1916-17. Since then we have placed another large specimen in a more open position, not far from an east wall and as by last autumn it had become well established, we hoped for success. In November we were tantalised by a moderate, very moderate, display of pink blossoms and since then frost has again injured the young growth and blackened a portion of the older leaves. Yet Mr. Bean in "Trees and Shrubs Hardy in the British Isles," speaks of it as "quite as hardy as Camellia japonica." Possibly we were unlucky enough to purchase a tender form of it, from a lower or more southern locality. A plant, even though true to name, may vary in its forms or varieties from tender to hardy. It may not be common knowledge, outside the botanic gardens, that the tea plant (C. Thea) varies enormously in hardiness. We tested many plants in the open, only to lose them in severe weather. At last we happened on a dwarfish variety, with small leaves, which always appears green and shining—almost smiling—after the severest frosts.—J. COMBER, *Nymans Gardens.*

THE ROSCŒAS.

THESE plants, which THE GARDEN has several times commended in the recent past, deserve to be much more widely grown. They grow with great vigour planted in 6in. pots and placed in a cold greenhouse without any particular attention. The flowers are beautiful and novel in form and the foliage after the flowers are past is a glossy bright green and very handsome—R. humeana in particular. I think the roscœas would be hardy out of doors in this climate, but having at present only a few plants, I have not yet ventured the experiment.—AUSTRAL, *Geelong, Australia.*

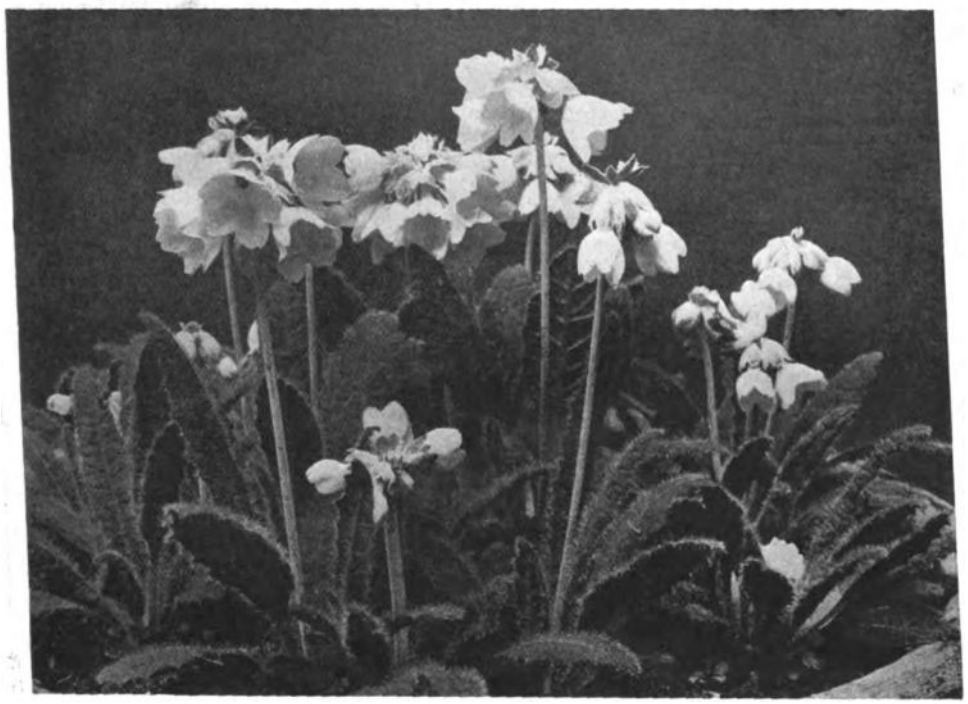
PRIMULAS FOR THE GARDEN

BY JOHN MACWATT.

THESE plants win more admiration every year, so I hope the following notes may prove of interest and use to those who, like myself, have been led to devote special attention to the cultivation of members of the genus primula. Few families of flowering plants display a wider range of habit. Take, for example, P. Littoniana, like a red hot poker; P. suffrutescens, like a miniature shrub; P. septemloba like a cortusa; and P. capitata, with its rounded heads of purple-blue flowers. The necessities of their culture are varied. While some kinds are among the most easily grown of plants, others—and among them many of those with which I shall deal now and subsequently—demand great skill and resource. They are, perhaps, plants for the enthusiast, and he who undertakes their culture must be prepared for not infrequent disappointments and failures before he attains to that intimate knowledge of their requirements which is absolutely necessary to success. But he will be abundantly rewarded for all his care by the unique beauty of the flowers he has reared, and their beauty will be enhanced by the knowledge that it comes to him as a reward.



PRIMULA REIDII, ONE OF THE MOST GRACEFUL OF ALL PRIMROSES.

P. SUFFRUTESCENS, A SUB-SHRUBBY SPECIES THAT SHOULD BE MORE OFTEN GROWN.

SECTION SPHÆROCEPHALA.

(With rounded heads.)

P. CAPITATA.—Much confusion exists in gardens regarding the true capitata, several other plants being cultivated under its name. Of those I have grown, four (P. capitata, P. crispata, P. Mooreana and P. lacteo capitata) are Himalayan, and two (P. pseudo-capitata and P. sphærocephala) are Chinese. The two last, although easily recognised as nearly allied to the Himalayan forms, can be readily distinguished by the much smaller corolla limb and the more globular head of flowers. P. capitata is the high alpine form and is all mealy. I have seen a double form of P. capitata.

P. MOOREANA is a large-leaved, large-flowered plant which flowers in late autumn. From true P. capitata and all others cultivated under its name, it may be distinguished by its large leaves, with coarsely reticulate, almost honey-combed snow-white under surface and the bright green upper surface.

All seem to be geographical forms of the same species. They like a well drained cool and moist position, but are best when grown under glass.

SECTION MUSCAROIDES.

P. PINNATIFIDA was collected by Forrest in Yunnan and introduced by Bees, Limited, in 1908. Although it comes from stony, peaty pastures, near the limits of perpetual snow, it is only half hardy. It produces 6in. spikes, bearing pendent fragrant flowers of a bright lavender above soft hairy oval leaves. This is a very peculiar member of the section, due to its possessing very cut foliage, sometimes so much so that it renders the plant almost unrecognisable. It is remarkable that this only occurs when the plant is growing wild and does not happen in cultivation.

P. DEFLEXA.—This is another very beautiful muscaroid primula with fragrant flowers of an almost periwinkle blue on neat stems.

P. CONICA.—This species greatly resembles P. Giraldiana, but has hairy scapes, a feature absent in the latter. I have grown large numbers of this species and although the majority of the flowers were lilac, a considerable number were white. The plant is destitute of meal.

P. GIRALDIANA.—Seeds of this plant were sent home from Yunnan by Forrest and plants were distributed under the name of P. muscaroides. It is quite a good species, with purple flowers in drooping heads on stems 8ins. to 12ins. high, rising above the oval, hairy, nearly erect leaves.

Digitized by Google

P. LITTONIANA is undoubtedly one of the most striking and beautiful of this section and one which is rendered highly attractive by reason of the scarlet bracts and lavender-lilac flowers, carried at the end of a spike varying in length from 6ins. to 24ins. The leaves are erect, oval in shape, being clothed with downy hairs and the stem mealy. There are two forms, the var. robusta, which is larger in all its parts, but with the flowers of an inferior colour to those of the more dwarf variety. P. Littoniana thrives in a light, rich soil, but like others of the section, is difficult to keep in winter on account of wet.

SECTION SOLDANELLOIDES.

P. SUTANS, from Yunnan, has large drooping fragrant lavender blue flowers in dense heads on white mealy stems 6ins. to 9ins. high. The flowers are also covered with white

P. VEITCHII IS ONE OF THE HARDIEST OF ALL PRIMULA SPECIES.

meal, so that it is better to grow it under glass. If exposed to rain the meal gets washed off the flowers, giving them a very blotchy appearance. Out of some hundred and fifty plants wintered in a cold house, a few were planted in the open and exposed to the weather. Those kept under glass and protected from rain had the corollas densely covered with white meal, but those in the open appeared darker and showed white markings. Taking one of the corollas that had not been exposed and putting it under a tap, I got the same blotching as shown by those in the open. I have seen this plant growing and flowering well in a rose border in partial shade.

P. REIDII is the only west Himalayan species known of this section and is one of the most delightful of all primroses, with its fragrant creamy white flowers carried 2ins. or 3ins. high on mealy stems, well above the densely hairy leaves. It is a perennial, but with me it always damps off after flowering. As it seeds freely it is best to grow it as a biennial.

Both plants described under this section have large, convolutely-shaped corollas and for their size the flowers are exceptionally large.

THE AUTUMN-FLOWERING P. MOOREANA.

SECTION OBCONICA-LISTERI.

P. OBCONICA is too well known to require any description.

P. SINO-LISTERI was collected by Forrest on dry, rocky pasture land on the western slopes of the Tali range. It is a most interesting species, not only from a botanical but also from a horticultural point of view. The woody rhizome is well developed. It is devoid of the irritant hairs met with in P. obconica. It is almost hardy and only requires to be placed in a house from which frost is excluded. It forms dense tufts of green, rounded, orbicular leaves and scapes generally carrying two tiers of white, pink or lilac tinted flowers. With me it is a very shy seeder.

MORE DELICATE THAN P. LITTONIANA IS P. CONICA.

Digitized by Google

P. WERRINGTONENSIS is a western woodland form of P. obconica. The flowers are rose coloured with a greenish yellow eye. It is quite a good plant if grown in the shade, but if cultivated in the sun the flowers are washy and bad in colour.

SECTION CORTUSOIDES.

P. VEITCHII is a very hardy and good garden plant. It is robust in growth and sends up a spike bearing whorls of flowers in tiers of a magenta colour, decorated with a golden eye and yellow anthers. The leaves are large with hairs of a reddish tint on the under side.

P. KEWENSIS, so well known to all gardeners, is supposed to have originated as a sport from P. Veitchii.

P. LICHIANGENSIS closely resembles P. Veitchii, from which it differs by the leaves on the under side not having coloured hairs. The flowers are larger and more drooping than those of P. Veitchii and the anthers are purple.

SECTION GERANIOIDES.

Fairly close relatives of the last comes the section geranioides, which includes :

P. HEUCHERIFOLIA, greatly resembling a cortusa and being a very fine hardy garden plant. It has soft, crinkled leaves and, on graceful stems about 6ins. high, bears pendent, bell-shaped flowers of rich purple. The foliage is deeply lobed, and

P. SEPTEMLOBA, a Chinese species, like P. heucherifolia, resembles Cortusa Matthioli, but with me is not hardy in the open.

SECTION CUNEIFOLIA.

P. SUFFRUTESCENS was introduced in 1884. This subshrubby species is rarely ever seen, although it is fairly hardy and not difficult to grow in light, strong, well drained soil. It has dark foliage and pink flowers in abundant trusses. In severe weather the branches are apt to die off at the tip, but in spring new shoots soon replace them.

P. RUSBYI, Greene, from the Rocky Mountains of Arizona and New Mexico, is a plant which has given a good deal of trouble to cultivators since its introduction in 1885. Its habitat is in a rich, moist soil at a comparatively low altitude. It is long in starting into growth, so one should be careful not to begin watering early. It has leaves about 4ins. long and about 2ins. broad, and produces a scape rising a little above the leaves, with an umbel of from two to ten flowers nodding to one side. The flowers, which have a peculiar odour, are of a crimson purple colour with an irregular line round the yellow throat of the corolla.

SECTION SIKKIMENSIS.

(A valuable garden section.)

P. SIKKIMENSIS is a well known plant with its long serrated leaves and stems sometimes as much as 2ft. high, bearing clusters of delightfully scented soft yellow flowers, coated with white meal.

P. PSEUDO-SIKKIMENSIS is a Chinese dwarf limestone form of P. sikkimensis.

P. FLEXILIPES.—The name of this plant is taken from the slender flexuous nature of its inflorescence. It may be of special value to those who prefer a smaller plant than P. sikkimensis, of which it may be said to be a miniature replica. The leaves are short, almost rounded and the drooping yellow flowers are sweetly scented.

P. SECUNDIFLORA was collected by Forrest on the Lichiang range in north-west Yunnan. In a shady border it does well and is exceedingly handsome when in bloom. It varies in height, in its native habitat being from 7ins. to 14ins. in height. The stem carries at its summit an umbel of drooping flowers of a deep crimson colour, the outside a little paler and the calyx of a ruddy purple, banded with white meal. It should be hardy as it is found at an altitude up to 15,000ft. I find it easy to grow and flower, but impossible to keep as the plants always rot at the neck after flowering. It seeds very freely.

(To be continued.)

CORRESPONDENCE

LILIUM SPECIES FARRER No. 1122.

SIR,—In THE GARDEN for November 7th, 1925, page 629, appears a note on "Three Interesting Lilies" from my esteemed friend, K. McDouall, accompanied by three illustrations. Two are correctly named, the third he gives as lilium species (Farrer No. 1122), and the Editor supplies the appellation L. nepalense after discussing the differences of opinion held regarding this lily's proper name.

For a quarter of a century now I have wrestled with the nomenclature of the lilies of Eastern Asia, and the species under discussion has given much trouble. After exhausting all the evidence I became convinced that the lily of Upper Burma and western China and that of Nepal, with which it has been confounded, are not only distinct species but belong to different sections of the genus, that the L. nepalense *D. Don* has a genuine funnel-form flower and is unknown east of Nepal, and that the lily of Upper Burma and western China, though often slow to assume its true shape, has reflexed segments, belongs to the Martagon group and is properly entitled to the name L. ochraceum bestowed upon it by the French botanist, Franchet.

The note in THE GARDEN goaded me to delve once more into this matter. It so happened that in the same number appeared an advertisement of Indian lilies by the Chandra Nursery Company of Sikkim in which L. nepalense was listed. I wrote to this firm offering to buy bulbs if a guarantee were given that they came from Nepal and not from Upper Burma. Also I wrote to the Forest Botanist at Dehra Dun, the only white man now living that I know of who has seen the Nepal lily growing wild on the Indian Himalayas, asking if he would state the shape of the corolla of L. nepalense. The courteous replies of both the nursery firm and the botanist have been received and are as follows :

Rhenock, Sikkim (Bengal)
Br. India,
22nd December, 1925.

DEAR SIR,—We thank you very much for your esteemed enquiry of the 21st November last, and in reply we beg to inform you that our Lilium nepalense is not collected in Nepal, but it is of Burmese origin.

Yours obediently,
(Signed) R. B. & D. S. PRADHANS,
Proprietors.

Dehra Dun,
22nd December, 1925.

DEAR SIR,—In reply to your letter dated 21st November, 1925, regarding nepalense, *D. Don*, I write to say that the flowers are funnel-shaped. I have a note on the sheet of my No. 2108A in this herbarium made soon after my return from the tour on which I collected the plant to the effect that the flowers in colour are as shown in Wall. Pl. As. Rar. III t. 291, and not as in *Bot. Mag.*, t. 7043. Wallich's figure is a good representation of the plant.

L. nepalense *D. Don* seems to be scarce in British territory, as the only other specimen (excluding a number which in my opinion are not Wallich's plant) in this herbarium is Duthie No. 6037 from "Rocks in the Kali Valley," collected 17-7-1886. Duthie got his plant in the gorge of the Kali river one march below Budhi, Byans. I found it also on steep rock ground.

Yours truly,
(Signed) R. N. PARKER.
Forest Botanist.

The lily sold by Messrs. Pradhans is not L. nepalense *D. Don*, but is the Martagon lily that masquerades in gardens under that name. It is the pseudo L. nepalense figured in the *Bot. Mag.*, t. 7043, it is the lilium species Farrer No. 1122 and its proper name is *Lilium ochraceum* Franchet.

Mr. Parker's information should settle the vexed question of the shape of the flower of L. nepalense *D. Don* and set at rest the whole question of the distinction between this lily, which is a true leucolirion, and that native of Burma and western China to which Don's name has been erroneously applied. The true *L. nepalense* is not in cultivation, neither has it been for some seventy-five years.—E. H. WILSON, *Arnold Arboretum*.

ALPINES FROM SEED.

SIR,—With reference to the notes in THE GARDEN on February 6th on "Alpines from Seed," there are one or two things that many people will not agree with. W. H. advocates the watering in of seeds after sowing. This will often prove disastrous. The best way is to dip the pots. That is, to submerge them to the rim and then take them out just as the surface begins to dampen. Seed pots should *never* be watered overhead, as this practice tends to "cake" the surface, and when the seedlings are up (*if* they arrive!), will probably aid damping off. If the plants to be raised are hardy, it would also be better to place the pots in a cold frame with lights on. Alpine seeds are often aided in their germination by a good freezing! To the compost, which must necessarily vary with the plant, there is one thing that should always be added—namely, *crock dust*. It should, in fact, always be visible in the mixture and an addition of crushed mortar rubble will often prove advantageous.—J. BIRKENTALL.

Digitized by Google

LACHENALIA NELSONI.

SIR,—In THE GARDEN of January 16th there was a note on Lachenalia Nelsoni, in which I was much interested, as I had bought a few bulbs (half a dozen) just to see what the flowers were like. I had read about them, but had never seen them. I was charmed with the flowers, also the leaves and stalks. The dark markings on them are both uncommon and pretty. The pots are most welcome in the house, as the flowers last a long time. One point I have never seen mentioned is that they are lovely as cut flowers and last a remarkably long time in water, and everyone who sees them asks the name. They are hardly known at all to the average person, and even some gardeners have never seen them. The bulbs increase very rapidly. I have now four pots—just coming into flower—and two boxes of the smaller bulbs which will be used as cut flowers, all this in about six years from about half a dozen bulbs.

Though only an amateur, I am greatly interested in the work. For some time I have been wanting to try winter-flowering begonias, but have not been able to get them. In the same GARDEN there is an excellent article on these begonias, so I now hope to try them. I have written about them to the name given in the article.

My reason for writing is that you ask readers to let you hear of their experiences, and the *increase* in bulbs may induce others to grow them, as one need only buy a very few to start with. Again, they are most valuable as cut flowers.

May I add that I get much useful information out of your paper each week, and when I have finished with it I pass it on to a hospital for sick soldiers, where some of the men work in the garden.—E. M. GREGG, *County Down*.

THE BLUE POPPIES.

SIR,—I was very much interested in your Editorial remarks on the beauty of meconopsis in the issue of THE GARDEN for February 13th, also in the two articles by Mr. Kingdon Ward on his latest finds in Tibet of new species of meconopsis. I think it is a pity that many gardeners fight shy of growing these meconopsis since most of them are biennials; but they are as easily grown from seed as most other biennials. The accompanying illustration shows a group of M. integrifolia which flowered in my garden in Perthshire last summer. These plants were raised from seed the previous year, planted out about the end of May and flowered the following season commencing in early May and flowering for six to seven weeks, after which they set a large quantity of seed. I find the best time to sow seed is in February. If sown in heat they germinate quickly. When the seedlings are large enough to handle they are pricked out into boxes about 2ins. apart, grown on in heat for four to five weeks, then placed in cold frames to harden off. One of the most important things in the cultivation of meconopsis is to get them planted out as soon as possible, for if they are kept too long in boxes and the growth checked in any way, they never make satisfactory plants.—A. HARLEY.

PERENNIAL PRIMULAS?

SIR,—I was much interested in your correspondent's letter in THE GARDEN of February 13th on Primula Littoniana, which with some gardeners is more or less a biennial. This primula has flowered with me during the last three years and I expect it will do so again this summer. The accompanying illustration of P. chionantha may be of interest to your readers. With some growers it flowers well the first year after raising from seed; but dies out soon afterwards. The photograph shows a plant of P. chionantha which was given to me six years ago and was taken last May when it was in flower for the sixth year. I find this species seeds freely and I do not trouble now to sow seed under glass, but every spring I throw the seed under some rhododendron bushes and by the autumn I have large numbers of healthy plants which are always in demand by my friends. This primula does not require such a damp situation as P. Littoniana, but does well in soil that suits P. Bulleyana and other like species. I grow one or two beds of this species and during the winter they are given a mulch of leaf-mould and manure, which they seem to appreciate.—A. H.

ROSEMARY.

SIR,—The note on rosemary by Mr. Clarence Elliott interested me greatly. I have been collecting varieties for some time, and I have six distinct ones. One bought as "gold," but very slightly yellower than the green; one the ordinary kind; one like the ordinary, but much fuller; one very strong and upright, with very white back to leaf; one very fine in leaf, not more than half as wide as usual; and also prostrata. I have also a variety which I got in an old Oxfordshire garden which then was much splashed with gold variegation, but my young plants have not yet developed this. I badly want the green and white variegated form, which I am told exists. I have also some very fine seedling lavenders, and have, by selection, got some of a good pinkish mauve and one with variegated leaves. I had one very interesting form from a wonderful garden above Locarno, which formed a sharply branched bush, the flower-stems also branching, but it did not survive the cold.—A. C. C., *Kent*.

THE DAINTY PRIMULA CHIONANTHA.

SIR,—Respecting the introduction of rosemary which Mr. Clarence Elliott mentioned in his interesting article in your issue of the 6th inst., Paxton's Botanical Dictionary gives 1548, the same being given in Loudon's Encyclopædia of Plants, the latter saying "Its introduction is beyond record, and was probably by the monks in the dark ages." For some years past I have admired a fine specimen of the prostrate form hanging down from a lofty bit of rockwork in the fine gardens of the late Lady Ardilaun, St. Anne's, Clontarf, on the northern shores of "Sweet Dublin Bay."—K., *Dublin*.

LARKS AND GREEN CROPS.

SIR,—A curious result of the recent fall of 4½ins. of snow here was that we had to net the green crops in the kitchen garden, particularly the broccoli, against a large flock of larks, which were stripping the leaves to skeletons. I have never heard of larks doing such damage. Driving them off was useless, as they returned at once. Our garden adjoins a large arable field, which, of course, was snow covered.—F. S. SAUNDERS, *Barcombe Mills, near Lewes*.

REV. J. JACOB—AN APPRECIATION.

SIR,—To our great regret we are informed of the decease of the Rev. J. Jacob, a gentleman whose memory will always remain green with us.

For many years he was a regular visitor and guest at our nurseries when our fields were in bloom, and his keen observation and advice about the value of so many varieties of tulips and narcissi were always greatly appreciated.

But we feel sure that all interested, amateurs and professional people alike, have greatly profited by the entertaining and interesting letters he wrote in your paper about the growing and forcing of the finer varieties of tulips and narcissi, flowers which he loved with all his heart, not to speak of the many valuable acquisitions of which he was the raiser.

If the love for these bulbous plants has increased generally during recent years, it is no doubt due in some small measure to the

A FINE CLUMP OF MECONOPSIS INTEGRIFOLIA.

Digitized by Google

efforts of Rev. Jacob, and not only the trade but the world at large has gained by it. We feel sure we speak in the name of the Dutch bulb trade when we express here our gratitude to him.—M. VAN WAVEREN AND SONS, LIMITED, *Hillegom, Holland.*

YELLOW TOMATOES.

SIR,—I was much interested in reading the note on yellow tomatoes by "W. F.," issue February 13th, page 108. Personally, I think it must be due to prejudice, mainly, that yellow-fleshed tomatoes are not more extensively grown—prejudice against the few old yellow sorts which did not possess much flavour; not so much against the ones now in the market, for the fruits are well flavoured, of beautiful shape and freely borne on the plants. I find that the yellow fruits remain fresh and sound of flesh longer than the red fruits. Furthermore, the yellow varieties are particularly good for late fruiting. For several years I have been a grower of yellow tomatoes and hope to grow more plants this year than in the past.—G. G.

ANEMONE NEMOROSA ROBINSONIANA.

SIR,—I notice Dr. Lloyd Praeger selected the above as apparently the best variety of the blue forms of our common wood anemone. While not despising the variety, I am rather in agreement with what Mr. E. A. Bowles says about it in his book, "My Garden in Spring," and think the variety Alleni is far and away better than Robinsoniana and, in fact, is the best of all the blue forms. Royal Blue is the richest colour, but is small. Blue Bonnett is very late, too pale in colour and, I find, not so large as Alleni. What I should like to see is a Royal Blue Alleni. Has anyone done any hybridising of these blue forms? If so, perhaps they will tell us something of the results.—H.

ROCK GARDEN ANNUALS.

SIR,—May I add a third to those mentioned by your correspondent "N. D. H." (THE GARDEN, February 6th)? This is Sedum cœruleum, a tiny little plant with starry blue flowers. It is not showy, some might call it insignificant, but it is very pretty in its modest way. It is, I think, the only annual sedum, and some seedsmen catalogue it as half-hardy, but it is quite hardy with me, although I have not found it ripen seed.—R. E. H., *North Somerset.*

THE SCOT IN DEVON.

SIR,—I read with interest "S. I. K.'s" note in your issue of February 13th, on the neglect of the fuchsia in the gardens of Devon. As a rhododendron enthusiast I am quite in agreement with him when he advocates planting rhododendrons, as it is admitted that by judicious selection of varieties in a mild climate such as Devon, Cornwall, some parts of Emerald Isle and many corners farther north, unheard of by some people, the rhododendron will give a continual display from early December until midsummer. None the less there is room in many gardens for the development of the fuchsia, both the species and hybrids and I hope to see it occupy a more prominent position in the near future, in gardens adapted to its simple requirements, than it does at the present time. As for camellias, "S. I. K." must know that these are fairly hardy plants and it is quite unnecessary to live in a favoured climate to grow them in the open. Fine plants of many varieties which flower freely every year, can be seen in the London parks, likewise at Wisley, which is by no means a favoured spot for attempting the growth of tender plants in the open. As a native of that land north of the Tweed. I note with amusement that my countrymen are being blamed for the neglect of the possibilities the climate of Devon presents to the enthusiastic gardener, in that they only grow the things they were accustomed to in Scotland. Many stories are told of the Scot, but he is seldom accused of the lack of foresight in embracing such opportunities as present themselves for gardening under such genial conditions as the climate of Devon affords. I can assure "S. I. K." that he can see all the plants he mentions in his own garden growing out in the open in some parts of Scotland, as freely as in Devon and Cornwall, in company with many more even less hardy. As I have within the last few days been asked to find another Scot for a head-gardener's place in Devon, I hope he will grasp the opportunities that "S. I. K." seems to think others have neglected.—R. FINDLAY, *Wisley.*

FREESIAS FROM SEED.

SIR,—I am surprised that your correspondent "T.," on page 72, threw away all his seedling freesias after their first flowering. As a freesia raiser I find it is impossible to judge the flowers in their first season, and I am sure "T." would have done better to have saved the corms and grown them on to their second flowering. Without referring to the previous correspondence on the subject of freesia seed, I gather that soaking the seed was recommended when sowing was delayed until the spring. I have only once tried spring sowing, and then had no difficulty in germination, but with August sowing I never find soaking likely to be necessary, but possibly by the spring seed may become hard.—F.

"PLANTING" SEEDS—WHICH WAY UP?

THE reader may be a little amused over the title of this article, since the gardener seldom "plants" his seeds in the generally accepted sense of that term; nor does he bother about a "right way" or a "wrong way" up position. Life is too short, and in practice the ordinary method of "sowing" must needs be followed. Yet the question has been raised as to whether a better and quicker germination, with improved subsequent growth of the seedlings, may not be obtained when seeds are sown "right way up"—if, indeed, there be a right and a wrong position. It is not altogether irrelevant to mention the case of the potato. Some attempt is generally made to place the sets or "seeds" with their eyes directed upwards, and the reason for this is well enough known. Is it not possible, then, in the case of the larger seeds, that it would be advantageous to place them in the soil in such a position that the young stem of the seedling would have no more to do than grow straight up and the young root straight down, without having to perform preliminary awkward curvatures, like so many gymnastic exercises? In pricking off, who has not rejected many a seedling because of undesirable twists in its slender stem?

To test the question, it is necessary to handle the seeds individually, to plant them, in fact, one by one. Obviously, only the larger seeds are suitable for such experimental work. Several tests have been carried out, with varying results. In general, there is a certain delay in germination when seeds are placed upside down, as has been proved conclusively for cotton and barley; but this delay has no noticeable effect in after growth and yield.

There must be some readers of THE GARDEN who have pondered over their seed-sowing, especially when dealing with a handful of large seeds, wondering whether they should be put into the soil this way or that. With the seed-sowing season again at hand, there comes the opportunity for those with an experimental turn of mind to test the matter for themselves. Observations which are made might then find their way into the pages of THE GARDEN, where I do not remember having seen the matter referred to.

By way of introduction, it may be helpful to suggest that the problem of the "right way up" position can only be appreciated by reaching an understanding of what lies within any particular seed. For this purpose the seed may be soaked in water and dissected, or it may be allowed to germinate to see what happens. A few examples may best illustrate the point. Let us look at the broad bean. Externally, there is a narrow black scar at the broad end of the seed, marking the point of attachment to the pod (Figs. 1 and 2). On germination the young root emerges close to this scar, since, within the seed, it occupies a lateral position and points towards one end of the scar. In Fig. 3 the seed coat and one seed-leaf have been removed to show the position of the root and the young curved shoot, which lies protected between the two seed-leaves. Germination is shown in Fig. 4, where it will be seen that the root has emerged close to one end of the scar, while the upward, arching shoot has also been withdrawn. In relation to germination, the interesting structural feature is not so much the scar itself as a small hole through the seed-coat which allows of the ready entrance of water, a supply of which is essential for germination. The position of this minute pore is easily ascertained if the seed be soaked in water and subsequently subjected to slight pressure between finger and thumb, when a drop of the absorbed water will ooze out through the pore. Now, the young root in the bean, and in a very large number of seeds, points towards this small aperture in the seed-coat, and since it lies close to the scar, the scar itself is the most easily visible means of knowing where the rootlet will emerge. And so the scar at the broad end of the bean seed is an indication that the "broad end down" position will be favourable to the immediate downward growth of the root without any preliminary curvature. Whether this position is distinctly more favourable than one where the seed lies on its side, which would seem to be the natural attitude, cannot be determined without making carefully conducted experiments. One may safely say, however, that there is a decided disadvantage in planting the seed "broad end up," and it is not

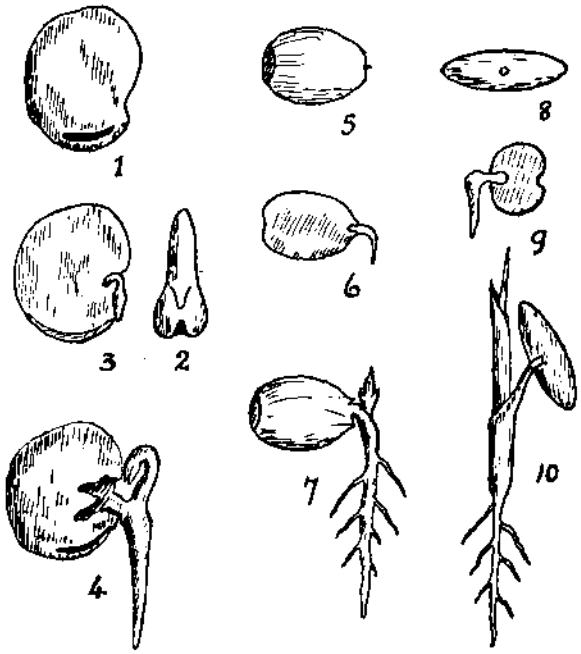
Digitized by Google

impossible that the frequent irregularity in germination of beans may be partly explained by some of the seeds getting into such a position.

The construction of the bean, thus briefly described, is illustrative of a great many seeds, where the scar on the seed-coat and the pore, towards which the young root points, lie close together. But sometimes the scar and pore are completely or partially hidden by a warty outgrowth of the seed-coat, as in the castor oil. The outgrowth seems to act at germination as a kind of sponge absorbing water from the soil, so again this end of the seed will be better placed down than up. Sometimes the outgrowth takes the form of a hairy tuft which also may act as a water absorber.

It is necessary to insist, however, that all large seeds should be examined on their own merits. For example, the scar on the acorn at its broad end is a mark on the outer shell which contains the single seed, and the actual seed-coat scar is at the opposite, narrow end. It is here that the rootlet emerges, and Figs. 5, 6 and 7 have been drawn intentionally to show what happens when an acorn germinates lying on its side, the natural position in which it would fall. The young root appears at the pointed end and has to turn through 90 degrees to grow downwards. As the shoot is withdrawn it also has to turn through 90 degrees to become vertical. Of the many causes of failure of the natural regeneration of our oak woods, there is definite experimental evidence which indicates a poor germination of acorns if they are placed with the sharp end pointing vertically upwards. Those who plant acorns in glasses sold for the purpose invariably make the mistake of placing the acorns upside down. The pointed end should dip into the water. It will be easily realised from the drawings that in a vertical position with the pointed end down the root has simply to grow straight down and the shoot straight up, appearing between the seed-leaves in a straight line with the root.

According to an old proverb, "Nature passes nurture," and one wonders, after all, if nature has not generally solved its own problem with regard to the position which seeds should occupy in the soil. Seedlings from very small seeds seem to right themselves as they germinate, and the chief precaution is to sow thinly. Among larger seeds, so many are flattened or winged or oval in shape that they must inevitably tend to fall on their side. Since this is the natural position, it would be rash to say that it is one which is unfavourable for quick germination and further growth. It is very important to remember that there is always some part of a seedling which is concerned in bringing the stem into its right position, so that root and shoot come into one line. This is well seen in the date, iris, lily and many others of their class. In Fig. 8 a date seed is shown lying on its side, exhibiting that tiny depression through which the rootlet appears when germination occurs. The section drawn as Fig. 9, on a larger scale, shows the young root turning downwards. But here, as in many other cases, the continued growth of that cord-like body which raises the seed above ground, really places the young shoot in a favourable position for further development, so that root and shoot are actually brought into one line, as shown in Fig. 10.



Each kind of seed, therefore, must be tested individually, and only the larger ones are at all suitable. For the coconut the question seems to have been settled by an experiment carried out in the West Indies. In March, 1913, fifty nuts were planted standing up and fifty on their sides. On October 24th, 1913, it was reported that of the fifty on their sides forty-six had germinated, and of those standing up only thirty had germinated.

The purpose of this article will have been served if it draws attention to an interesting point requiring further experiment, and it is hoped readers of THE GARDEN will relate their experiences.

J. R. MATTHEWS.

FIG CULTURE IN THE OPEN

THERE must be in many gardens suitable places where figs will thrive, especially if a little protection be afforded during a spell of severe weather. In the neighbourhood of Worthing in Sussex figs are cultivated on a fairly large scale, and here it will succeed as a standard, but farther inland it should be planted at the base of a wall with a south or south-west aspect, unless an open, warm position can be chosen.

Most failures can be attributed to a rich rooting medium, this causing a lot of gross wood to develop and very little fruit. The planting of fig trees is best carried out in the spring, standards and espaliers being selected for the more open situations and fan-shaped for walls. Ordinary garden soil is quite good enough for figs, but it ought to be trenched 3ft. deep and a good layer of drainage placed in the bottom, chalk being a suitable material for this purpose. As the operation proceeds, a liberal sprinkling of old mortar rubble and pieces of brick can be incorporated, as good drainage is essential.

A restricted root-run is advisable, and for a start a border 3ft. wide will be ample, and unless the border is near a hard gravel path, a few pieces of corrugated iron let down in the soil will help to curtail the wandering roots, and thereby induce fruitfulness in the early stages of the tree's development. Later on, when the fruit is swelling, a weekly application of liquid manure will be beneficial. Only one crop of fruits can be expected from the open ground, and any fruits that appear in the autumn with no prospects of ever ripening are best removed. It should be borne in mind that fruit is produced along the growing branch, and this, of course, has some bearing upon the method of pruning. Severe pruning is often a mistake, and the usual method is to cut out old growths, to prevent overcrowding, and replacing them where necessary with new wood. This can be done about October, or when the fruit is gathered. Towards the end of March a further overhauling may take place, when the growths are carefully regulated and made secure. It will no doubt be advisable to remove a few more shoots, so that there will be space for the development of fresh growth.

One often meets specimens that have exceeded their allotted space, with plenty of healthy growth on the top and nothing but bare stems in the centre. This can and should be remedied by encouraging new growths from near the base of the main branches, Such shoots eventually make better wood than suckers, which are occasionally freely produced from the base of old trees. It is best to remove these in the early stages. The object of pruning is to keep the growths from being overcrowded and, like peach trees, much can be done by judicious disbudding during the growing period. Any shoots for which there is no room can be removed before they have made much headway, and other vigorous growths should have their centres pinched out when they are 18ins. or so in length.

It often happens that fig trees, and especially young ones, become extremely vigorous and fail to bear any fruit. When such is the case root pruning must be resorted to, and in some instances the tree can be lifted and replanted immediately. All the thick roots are severed, particularly those going down in the soil, while others near the surface and of a fibrous nature are encouraged and kept fairly near the top.

During a spell of severe weather it will be advisable to protect the trees if growing in less favoured districts. This is done by covering the root-run with straw, or fern bracken, and employing thatched or straw hurdles for the branches. No protection is needed unless the weather is very cold, and then the material should be removed directly it becomes mild. The two best varieties for outside are Brown Turkey and Brunswick.—T. W. B.

POTATO CULTURE

AS with every other crop, the first consideration in the cultivation of the potato is the treatment of the soil. Undoubtedly the best potatoes are grown on rich light loams, but very few gardens are found in which potatoes are not grown to a greater or lesser extent. Except almost pure sands and the heaviest of clays, potatoes will grow in any soil, providing it is treated properly.

Where possible, the soil should be trenched or double dug—a long, hard job, but a job to "clear the cobwebs from one's mind" and "ease the muscles."

It is better, whenever possible, to dig deeply or trench in autumn, leaving the soil rough and lumpy for the frosts to break down. Another advantage of leaving rough for the winter is that the birds will scratch in the rough soil and consume any grubs, eggs and pupæ which are near the surface. If any decayed vegetable matter can be incorporated when the soil is turned over, so much the better, and any new manure, especially on heavy soil, is best put in during autumn and winter.

In early spring the soil should be forked over and rotten manure incorporated if none was worked in earlier. The best returns from potatoes have been obtained by using decayed manure with the addition of artificial fertilisers.

We have obtained good results by adding manure at the rate of 12–15 tons per acre, supplemented by the following mixture, hoed into the soil before planting:

3lb. superphosphate of lime
¾lb. sulphate of ammonia
¾lb. sulphate of potash

per rod.

Presuming the land has been well prepared for the crop, we must turn attention to the "seed."

Five or six weeks before planting time the tubers should be boxed up, placing them one layer deep in shallow boxes with the rose end—that is, the bigger end, containing the most eyes—uppermost. These boxes should now be placed in a cool, light place for the potatoes to sprout. If kept too warm the shoots will grow too quickly, while if kept in the dark, long, weak, straggly shoots will be produced.

This simple treatment is important. In the first place, increases in crop to the extent of 2 tons per acre have been produced by sprouting the tubers. Secondly, only those tubers which have sprouted are planted, and thus we discard tubers which may be infected with disease. Finally, the plants have started growth, and get away quicker when they are planted out.

There is often a great deal of controversy regarding the value of cutting the sets. With seed sized-tubers it is far better to leave them alone; but with large sets one often has to cut the tubers to obtain sufficient to plant the plot. Where it is necessary to do this, always cover the cut surface with plaster or lime and, if possible, plant immediately after cutting.

The time to plant is a matter for individual decision. The season for planting extends, as a rule, from February until May. Main-crop potatoes are usually planted in late March in the very south, and later the farther north we go. The point to bear in mind is that we do not want the plants above-ground until danger of sharp frosts is past. With early potatoes the case is different. Many gardeners who possess a warm, sheltered border commence planting at the beginning of March. Such early planting necessitates covering the ground with litter or bags on cold nights, but often it is considered worth the trouble on account of the earliness of the crop.

Easter week-end is, in the Midlands and South, considered by allotment-holders to be *the* time for planting potatoes and, the weather being suitable, this time is not at all out of season, although, of course, the date varies.

The distance allowed between sets and rows also varies with the class of potatoes being grown. For instance, first earlies may be planted as close as 9ins. between the sets and 18–20ins. between the rows, whereas strong-growing main-crop potatoes need 12–15ins. between the sets and 2ft. to 3ft. between the rows. Again, the purpose for which the potatoes are grown will to some extent control the distance allowed. To illustrate what I mean, it has been found that to obtain the greatest crop for a *given area*, main-crop potatoes should be planted 12ins. by 24ins., whereas to obtain the largest yield *per plant* the distance should be increased to 15–18ins. by 36ins.

Well, I have spent a considerable time dealing with preliminaries, so now I will presume that the ground is prepared and we are about to plant our sprouted tubers. There are many ways of planting, but I will only deal with two or three of the commonest.

'Dibbling in" a very common practice, is one to be deplored, especially on heavy soil. The potatoes are placed in holes, the sides and bottom of which are hard and difficult for roots to penetrate. I think most people will agree that the best results can scarcely be expected from plants dibbled in. On free-working soils drills may be drawn with the hoe, and this is one of the best methods which can be adopted. On heavier soils a spade may have to be used, but use a "stock hoe" in preference to the spade. Another excellent method where the soil has been previously well dug is to fork over the ground, putting the tubers in as the work proceeds. By following this method the tubers are placed in loose soil, into which they throw out roots very readily. Lastly, a method which should never be adopted except in exceptional circumstances, such as where the water level is very dangerously near the surface soil, is that called, I believe, the "lazy bed system," which consists of placing the potatoes on the surface and covering them by earthing up.

After planting, hoeing should be attended to, keeping the soil clear of weeds and drawing a little soil up to the young plants. The next operation calling for attention is earthing up, which is usually performed when the plants are 6ins. or so high. There are several advantages of earthing up, the principal one being that loose soil is placed round the plant, into which the young underground stems, which produce the tubers, can run; and that the tubers are protected from the light, which would discolour them. Another point is that the layer of soil checks the spores of blight and to some extent prevents them reaching the tubers when they fall from the leaves.

Before earthing up, fork between the rows and break up the soil. Just a detail, but one which makes all the difference between earthing up with a moderate amount of labour and real hard work. Use the hoe for earthing, and make a broad-topped ridge, so that some of the rain may soak through the ridge and not all run off into the gullies.

After earthing, hoeing, of course, cannot be managed; neither, as a rule, is it necessary, for the potato tops will smother all but the strongest weeds, which must be hand pulled.

The last item connected with potato growing that I wish to mention is spraying. I fancy I can hear murmurs of disapproval from many people as I write this, but my answer is, the commercial growers—or, at least, many of them—believe in spraying, and is it likely that such growers would spend money on this operation if it were not necessary?

I know that many crops are raised every year without this attention, but, especially in a wet season when the potato blight is rampant, it is a safeguard. Of course, spraying with Bordeaux or Burgundy mixture will not *cure* "blight," but it will go a long way towards preventing its spread.

N. D. H.

ROSE WILLIAM ALLEN RICHARDSON.

IT is nearly forty-eight years since Ducher sent out William Allen Richardson, a noisette rose bearing very deep orange-yellow blooms of moderate size, borne in great freedom. Its introduction caused somewhat of a stir in the ranks of rosarians, and, though only a youth at the time, I well remember seeing the wonderful coloured flowers on a cottage wall. I think its chief fault is that the blooms lose the deep tint when exposed to the sun, and are paler; indeed, almost white at the edges after a few hours in glaring light. Notwithstanding this, and the immense number of sorts that have appeared since 1878, William Allen Richardson, grown either as a climber or standard, is very charming, and something to be proud of. It is one of the earliest to open in June, and one of the last to leave us in the late autumn. One may often cut exquisite, deeply tinted sprays of blooms and semi-opened buds, late in October in mild seasons, of which cold nights have intensified their beauty. In summers when we have had more than our usual quantity of rain and dull weather, this rose shows what it is capable of—no bleached blooms, but a rich blending of orange and yellow and buff, and with it all, a delightful fragrance and beautiful foliage. I occasionally meet with people who "run after" novelties, but cannot find in their heart to dispense with W.A.R., when new arrivals are discussed. W. LINDERS LEA

Carters Testing Grounds and Laboratory at Raynes Park.

SEEDSMEN BY APPOINTMENT

ECONOMY *of* GOOD SEEDS

FOR over fifty years Messrs. James Carter & Co. have carried out thoroughly, in every branch, the Analysis and Testing of Seeds, hence the well-known trade-mark, "Carters Tested Seeds."

Many years before the war Carters Seed Testing Laboratory was recognised as the best equipped in the country, we believe it still holds that unique position to-day.

The remarkable successes achieved by Carters Tested Seeds on the Exhibition tables throughout the country, prove that to obtain Vegetables and Flowers of the highest quality, it is essential to purchase seeds that have gone through the searching tests of experts in the Laboratories and Testing Grounds,

Vegetables and Flowers grown from Carters Tested Seeds cost no more for cultivation than ordinary strains, and the results prove of considerable advantage to Horticulturists.

FLOWERS.

PERENNIAL ASTERS AND MOON DAISIES.

EVERYBODY can grow the former and the majority of garden lovers can succeed with the moon daisies, several varieties of which are so beautiful. Perhaps it is because the first named are so easily grown that so many plants are badly cultivated. If one meets with one well grown collection, against this, one sees half a dozen badly grown—outside our nursery gardens. I have recently dug a small herbaceous border in which some clumps of Michaelmas daisies are growing. Although planted there one year ago, sucker shoots are permeating the soil quite 1ft. on all sides. These are to be sacrificed in part, only a few being retained. Inexperienced cultivators may have to deal with similar plants. If left undisturbed for another year such clumps would become overcrowded. If dealt with as suggested, next year's display will be a grand one, and the third year lifting, division and replanting will be more of a pleasure than a task. If single-stemmed plants are preferred, extra care is necessary in regard to soil suckers. With regard to the moon daisies (Chrysanthemum maximum), a richer rooting medium is an advantage, and old roots should not be allowed to encumber the soil. Such plants bear puny flowers, not to be compared to those big, pure white, broad-petalled beauties borne on plants young and growing in a good soil. When dividing up old roots all the inner portion should be discarded and the outside parts retained. For the benefit of the inexperienced I may say that three splendid varieties are Mrs. C. Lowthian Bell, M. Prichard and King Edward VII.—HANTS.

ANNUAL ASTERS.

NEARLY everybody who has a garden or a plain plot of ground grows asters. Perhaps I ought to say, makes attempts to grow them, as all do not succeed in growing the plants to perfection. It is astonishing the great quantity of flowers some beds of plants will bear, and when the plants are really well grown from the seedlings to the flowering stage the quality of the blooms is very high. There are three important items connected with the cultivation, namely, raising the seedlings, the border soil, and the planting with after-treatment. It is absolutely necessary that the soil in which asters are grown is sweet and free from fungus. The tiny seedlings thrive in a sweet leaf-soil mixture, but one in which there is any rotting sticks should not be employed. Use new boxes or, for preference, pots or pans for the first crops. The seeds should be sown thinly and lightly covered with rather drier soil. When the seedlings possess two rough leaves, transplant them and use, if possible, some old mortar rubble. A high shelf in a greenhouse, or a frame which can be protected from late frosts, will be suitable at this stage. A cold frame should be used

RYDERS SEEDS
in 2d Packets

WHEN, many years ago I decided to sell my Quality Seeds in Small Quantities, one chief reason was the intense delight it would bring to thousands of gardeners who desired a variety of bloom, a mass of colour, and that pot-pourri of fragrance we associate with an old-world garden. Ryders 2d. Packets enable you, whatever the size of your garden, to plant it with the seeds of *every* flower you love.

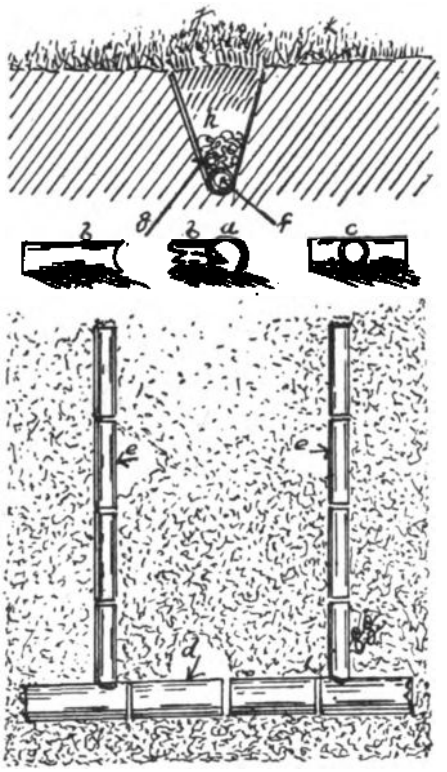
for the hardening of the young plants. In the meantime the border soil should be manured, left lumpy on the surface, the latter being just hidden by a dressing of lime. Fork in the lime late in April and plan the asters during the second and third week in May. Successional batches of plants should be raised in cold frames and the last one in open ground.—CHRISTCHURCH.

MISCELLANEOUS

LATE DRAINING WORK IN GARDENS.

THE recent heavy rains prompt me to write a few notes on the subject of draining in gardens. We all know that if soil remains long in a water-logged condition, or even soddened, early crops are difficult to obtain. Frequently, one puts off doing certain work until it is almost too late to



accomplish it to the best advantage. Every owner of a garden has been able, lately, to note the soil conditions and where it seems to be the best policy to put in drain pipes the following hints will prove useful to the inexperienced. It is never wise to lay drains carelessly; they are buried deeply, as a rule and once laid they should not require much attention afterwards. In broken ground the difficulty of attending to faulty drains is not great; in the case of lawns it is. New lawns will be formed, mainly from grass seeds, a few weeks hence; if there has been hesitation as to drainage matters hitherto, there should not be any now where naturally wet soils obtain. Drains should not be laid on a too sharp incline; a medium one is best. In the sketches, *a* shows the end of a main drain; *b*, *b*, and *c*, the way to connect side drains so that the water flows into the main. The plan of laying the main drain, *d*, and the side drains, *e*, *e*, connecting with it, is shown below. The section of opened drain and pipe, *f*, with rough material, *g*, and the finer soil, *h*, are shown above. The soil must be higher, also the turved, *i* and *j*, than the normal level, *k*, when open drains

Launching an offer of Seeds for trial.

Free and Post Free.

We launch this offer with much the same feeling in which we should approach thin ice—gingerly—because the offer might be thought to somewhere hide the cloven hoof.

But as we are neither asking for money nor making any conditions whatever in offering to send seeds free to anyone who cares to ask for them, it is difficult to see where the hoof could be hidden.

In the hope of getting into touch with a larger number of gardeners than we now have the pleasure of serving, we are sending to all applicants, free and post free, one packet each of three remarkably good vegetable seeds:

BEETROOT—BAKERS' SELECTED GLOBE. A beautifully formed round beet with a conspicuously thin tap root. . . . .

PARSNIP—GOLIATH. The biggest and best Parsnip that has ever come our way. . .

ONION—MONARCH. The largest growing, best flavoured Onion among those that really keep.

All we ask is that only responsible people will send for the seeds and that they will do their best with them when they get them, because it is only on results that we can hope for the distribution to benefit us.

Where results are good we hope that the grower will be encouraged to learn for himself what Bakers' other seeds are like and so bring grist to our mill.

For our part we can assure all such ladies and gentlemen in advance that the behaviour of the three varieties of seeds we are sending may be taken as a trustworthy guide to the growth and production of all the seed we sell.

Bakers

SEED & FLOWER FARM,
CODSALL.
Nr. Wolverhampton.

To anyone who is diffident about sending for the free seeds we shall be glad to send a copy of our complete Seed Catalogue. In many ways it is an unusual list—more informative than most—certainly more comprehensive and with something about it that might be called the "human touch," as distinct from the cut and dried, soulless sort of production most of us are used to.

AUTUMN and WINTER BEAUTY

In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

Seedlings Thrive and Don't Die

off after being transplanted owing to root disturbance or breakage, if brought up in Patent

MILLIONS SOLD **T. P. SEED RAISERS** NO SLUGS

because no disturbance can take place.

FOR ANNUALS, as Godetias, Clarkias, Larkspur, etc., *USE* BABY T.P. SEED RAISERS (measuring 1¼in. across by 2in. deep). Sow 2 or 3 seeds per Raiser, pull out to strongest. It will develop strong root growth till planting-out time comes, when Raiser (by that time rotted) will peel off, allowing seedling to be put in soil without knowing it has been touched.

FOR SWEET PEAS *USE* T.P. PEA RAISERS (size 1¼in. across by 4½in. deep). Sow 1 seed per Raiser. You will be delighted with good root action and quick development after planting out.

You get stronger plants, guaranteed to grow well with less labour.

T.P. Raisers take up much less room and retain moisture thus requiring less watering, are easy to handle in bulk and do not break, and ensure good plants, thus saving seed wastage.

PRICES in U.K., cash with order, carriage paid—

Baby" T.P. Seed Raisers, one strong seedling tray with 54 **"Baby"** Raisers complete. 1 for 2/6; 2 for 4/9; 3 for 6/9; 6 for 13/-; 12 for 24/6. **Refills ("Baby" size),** 108 for 2/7; 216 for 4/10; 324 for 7/3; 540 for 11/3.

T.P. Pea Raisers, one wooden box having hinged side with 48 Raisers complete. 1 for 4/3; 2 for 8/-; 3 for 11/6; 6 for 22/6.

Refills. Pea size, 100 for 3/-; 200 for 5/9; 300 for 8/3; 500 for 13/6

Order NOW from your Seedsman. If he does not stock, send direct to Sole Makers

Side of Baby Raiser removed showing root action of Larkspur

are filled; then, as the soil settles down, the turf over them will be level too.—GEO. GARNER.

TRANSPLANTING WITHOUT ROOT DISTURBANCE.

DISAPPOINTMENT is sometimes experienced by gardeners in the raising of annuals, for on planting out a healthy batch of seedlings from the seed boxes into their permanent quarters the young roots are broken off, and if the weather is at all warm and dry the plants flag badly and take some days before they recover from the check. It is almost impossible to remove young plants from an ordinary seed-box without disturbing the ball of soil, but this difficulty can be overcome completely by the use of one of the special seed raisers which are now on the market. Two excellent seed-raising contrivances which have proved highly satisfactory are the baby "T. P." Seed Raiser and Fibrex Pots. The former is a small edition of the well known "T. P." sweet pea seed raiser. It consists of small square cardboard boxes, fifty-four of which fit exactly in a special seed tray. The boxes are filled with soil and a few seeds sown in each. After germination the seedlings are reduced to one in each box, and, as the seed raisers are retentative of moisture, the soil keeps moist and the seedlings grow apace. By the time the sturdy young plants are ready to plant out the cardboard will have rotted and can be pulled away without disturbing the ball of soil, and the seedling can be planted out without receiving any check. Fibrex seed raisers differ in that the small square pots are made of a fertile medium which, when dry, is hard and unbreakable, but when moist becomes soft and tenacious so that the roots actually become embedded in the pot The plant feeds on the pot, and when the seedlings are ready to plant out a hole is made and the entire pot is dropped in without any disturbance to the root action. Both these seed raisers save time and loss of seedlings.

SPADES AND SPADE WORK.

WHAT an old favourite pipe is to a smoker, so is an old spade to a gardener: he feels lost without it. There is a great difference of opinion among gardeners on the subject of selecting s spade. Some consider those with a wide blade to be more satisfactory for digging and trenching, while some prefer those with a small blade, claiming that more work can be accomplished with this type. The chief thing to observe, however, is not so much the size of the blade, but, rather, the weight of the spade. Amateurs in particular frequently select one that is really too heavy to be useful. A good deal of muscular work could be avoided if the implement used was not so overweighted.

Another point to notice when selecting a new spade is, that those with a D riveted handle will last much longer than those without, also the "tread" should be a fairly wide one, as this gives greater scope and power in the using of the foot. Deep cultivation is the result of good spadework, and this always improves the soil, giving greater fertility.

Bastard trenching is one of the best methods of turning over new ground, and is the easiest to perform. Mark off a plot about a yard wide and a foot deep halfway across a 1one end. The soil taken out is left at the same end to fill in at the finish. Dig up the bottom, at the same time work in any manure or refuse available. Now turn up the next yard of top soil on the top of it and shovel out the bottom of the trench. Continue on in this manner until the whole plot is finished.

Allotment and kitchen gardens should be trenched in this manner every two years at least to get it into "good heart." Once the

Digitized by Google

soil is got into this state of cultivation, it is capable of producing both larger and better crops.—G. BARTON.

BORDERS NEAR DWELLING-HOUSE WALLS.

IN small gardens where there is not much room for growing plants and flowers, the owners are often tempted to have flower borders against the dwelling house. This is not always advisable, because the necessary watering may keep the soil in a too moist condition for the well-being of the foundations. Damp courses will prevent any moisture rising in the wall, but the mischief occurs below that point and then there is a constant dampness under the floor boards, notwithstanding ventilating bricks. But there are many kinds of plants—some of which are named below—that are suitable, and from the growth of which no harm to structures can arise. Ivy, even when clipped and kept at a height of about 2ft. above the soil, will prove beneficial in the case of naturally damp quarters. I have known ivy keep a wall dust dry after planting, which was, previously, always moist. The ivy never required any water and, even after heavy rains, the soil and wall outside were found dry. Azalea Hinodigeri, a hardy Japanese species, carmine flowers; Cornus canadensis grows 8ins. high; Daphne Blagayana; D. Cneorum major, grows 14ins. high; Erica carnea; Hypericum calycinum, 6ins. high; Veronica cupressoides, 1ft. high; Veronica Hectori, 18ins. high, are a few suitable low-growing shrubs that do not require much water. A bare border in summer may be occupied by petunias, saxifrages, or mesembryanthemums; these, too, do not need much moisture at their roots. It is a question of position, taste and due preparation of suitable plants.—CHRISTCHURCH.

NATIONAL CARNATION SOCIETY.

WE have been asked to announce that in connection with the above Society a gift scheme has been set on foot. It is proposed that all subscribers of 5s. will receive six carnation layers, while those subscribing 10s. and over will be presented with twelve. These layers are being supplied by the leading carnation growers throughout the country.

This offer is designed to stimulate interest in the work of the Society and also to encourage the more widespread culture of border carnations. It is to be hoped that the offer will be fully appreciated and taken advantage of, and that the Society will benefit by a large increase in membership.

CATALOGUE RECEIVED.

Messrs. Carter and Co., Raynes Park, S.W.20.—Farmers' Guide Book for 1926. Well illustrated, with numerous descriptive notes which should prove helpful to all engaged in farming pursuits.

Messrs. Andrew Ireland and Hitchcock, Marks Tey, Essex.—A Catalogue of vegetable and flower seeds. A long list of sweet pea varieties, including a number of recent novelties, is included.

Messrs. Godfrey and Son, Exmouth, Devon. —A short and concise list of some of the best varieties of chrysanthemums for all purposes.

FOREIGN.

Messrs. Anthony C. van der Schoot, Hillegom, Holland.—A catalogue of gladioli, hardy perennials and roses.

M. H. Correvon, Floraire, Chêne-Bourg, Switzerland.—A List of Seeds of Choice Alpines, the majority of which have been collected in the Alps.

Wilhelm Pfitzer, Stuttgart.—General Seed List, including all hardy plants, and roses. Numerous illustrations appear throughout the text.

M. R. Ferard, 20-22, Rue de la Pepinière, Paris.—List of Seeds for 1926 sowing.

The Pink Garden Beautiful

WAKELEY'S *Celebrated* Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

AUTUMN and WINTER BEAUTY

In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

THE BARNHAM NURSERIES, LTD., BARNHAM, SUSSEX.

Notes from Maidstone

SPRING PLANTING.

We get many letters from customers asking if it is too late to plant Fruit Trees and Roses. So far from this being the case, nurserymen do most of their own planting at this time of year. Fruit trees planted now will be much more likely to fruit than if put in in the autumn.

All orders are despatched the day after receipt.

George Bunyard & Co., Ltd.,
The Royal Nurseries,
Established 1796. Maidstone.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.

In the *Field*, a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6.

Coloured illustration sent on application if THE GARDEN is mentioned.

A COMING FLOWER

THE gladiolus is one of the flowers that has made a sudden spurt in general popularity, and certainly not without good justification, for it is easy of cultivation, fine in colour, upstanding in growth, and the flowers last well—four qualities very much to its credit. This is the first gladiolus number of THE GARDEN, and we hope in future to make it an annual event, for progress in the evolution of this flower is already rapid and is sure to increase as time goes on; in fact, it is worthy of having an issue devoted to it. Incidentally, could some scholar clear up the question of pronunciation of the name? I see that most modern authorities accent the first "i." It is a diminutive of the Latin "gladius," a sword, in which the accent is certainly on the "a." Surely the correct stress is "GLADĬŌLŬS"? This may make rather a difficult word to pronounce, but if it is the correct stress, it should be used. I find that the word Gladiolus is found in a Saxon manuscript dated 1000 and that it was certainly in use in the middle of the sixteenth century. On the other hand, I cannot find out for what flower the term was used; perhaps it was the flag iris. At least it must have been something with similar sword-shaped leaves.

Readers of THE GARDEN may remember the article on South African gladioli species, printed in the issue of July 11th, 1925, and the illustrations of them in their native habitat that accompanied it. They show a grace of growth and an unstudied elegance which, unfortunately, our garden forms lack. This, to my mind, is the only real fault that our present-day gladioli possess: they do look stiff and self-conscious, particularly in the large-flowered section. This has been partly rectified by the introduction of the primulinus hybrid; but there are signs that breeders are in this case also beginning to sacrifice shape of plant for shape and colour of flower. On the other hand, I hope and believe that new strains will be introduced by using new species as these become available, for imagine a plant with the present colour and shape of flower but without the suggestion of a soldier on full dress parade—spick and span without a doubt, but ramrod-like in its stiffness. Those illustrations of the species have made me long to try them out in less formal positions in the garden on a hot, dry bank among low berberis, where the modern variety would look out of place. I should say that, although much less has been done to improve the plant, there is no genus on which the keen hybridist could work to better advantage. Incidentally, several firms specialise in selling gladiolus seed; they are interesting to raise and there is always a chance of finding a wonderful seedling among a batch.

This complaint about their stiffness does not mean that I have little use for them in their present form in the garden: far from it. There is hardly a flower that is more effective during August or September, but it needs to be planted carefully, with due regard to background and surroundings. Some may differ, but the general method now is to eschew the single plant or twos or threes and plant them either in masses or in clumps of at least a dozen. A single spike will look incongruous when seen among anything not so well groomed as itself. I prefer not to see them in a herbaceous border even in a large clump; somehow, they do not seem to fit into the picture; but that is a personal opinion. Others prefer them in such a position just for their stateliness. On the other hand, nothing looks so well as a bold mass against a sombre background or a long border at least 3ft. in width filled with them at the base of an old wall, where they can stand with their backs to the wall and there is nothing untidy or fluffy to take one's eye off their primness. Wherever they are planted it should be remembered that in their present state gladioli are formal flowers, and so should have a position fitting to their dignity. In all cases a reserve border should be planted where spikes can be cut for house decoration, for their position as cut flowers is in the very first rank. Few flowers have such a uniform purity of tone, whatever the colour may be, or such a luscious rich texture of petal that makes so wide an appeal to our senses. Everyone should make a mental note to devote at least a tiny patch of their garden to gladioli.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

SHRUBS FOR WALLS, by W. J. Bean.

SAXIFRAGES IN GENERAL, by Dr. R. Lloyd Praeger.

SOUTH AFRICAN GLADIOLI AND THEIR HAUNTS, by K. C. Stanford.

NOW THAT THE GROUND IS DRYING AFTER THE SOAKING IT HAS RECEIVED DURING THE PAST TWO MONTHS, REMEMBER THAT THERE IS STILL AMPLE TIME TO PLANT ALPINES, HERBACEOUS PLANTS, TREES AND SHRUBS.

Digitized by Google

IMPRESSIONS OF SOME OF THE NEWER AND BETTER GLADIOLI

PROBABLY I shall be repeating what most readers of THE GARDEN know to be true, if I say that public interest in that beautiful flower, the gladiolus, is steadily increasing in the British Isles. Greater keenness is being exercised in the choice of varieties (a sure indication, this), and a wider interest is noticeable in novelties and the newer varieties. It is significant that more new gladioli are introduced each year than new roses, sweet peas or dahlias, if one includes novelties from all sources. America (where the gladiolus holds a much higher position in public esteem than here) is the birthplace of the majority of new kinds, although a large number hail from Europe and some from Australia.

Enthusiastic and confident though I may be that the gladiolus has a far brighter future than a past, I am not one of those who believe that a greater popularity for it spells a corresponding decrease in favour for such firm favourites as the rose, sweet pea or carnation. Yet, when it is more generally realised how very easy it is to grow good gladioli, how adaptable they are and what great improvement has been registered by many of the newer varieties, many amateur gardeners who now vaguely imagine they are difficult subjects to grow will surely become gladiolus enthusiasts. Again, when one remembers the fact that, broadly speaking, the measure of popularity a flower may attain is governed by the degree of pleasure it affords in proportion to the time and money expended on growing it, one cannot help being quietly confident of the great future the flower has. It appeals equally to the man of small means and a small garden, as to those more fortunately situated in these respects; moreover, there is something aristocratic (I cannot think of a better word) about a vase or basket of gladioli, whether they are found in cottage or mansion.

Maybe there are some readers of THE GARDEN whose familiarity with gladioli is bounded by such varieties as brenchleyensis, Empress of India, etc., and who would like to try some of the newer and better kinds. To these I venture to give my personal impressions of some of the fairly recent introductions, which are, nevertheless, within range of modest purses.

ALICE TIPLADY WILL BECOME A GREAT FAVOURITE.

It is said that every rose has its faults, and in the case of the gladiolus this probably holds good and to a greater extent. There is a very mixed medley of types and species, crossed and intercrossed, forming the ancestry of modern varieties. Consequently, a comparatively wide divergence of form and habit may be expected. This is no detriment, rather the reverse, for there are enough forms, shades of colour and flowering periods of the year to be found in the many hundreds of catalogued varieties to satisfy the most critical. The two most popular present-day types (or collections of types) are the large-flowering hybrids and the primulinus hybrids. As to what might be termed ideal form in either is beyond the scope of this article, although I may, perhaps, endeavour to deal with it later.

The following list embraces varieties which I have grown, one or more seasons, and which have favourably impressed me after careful comparison with the best of the standard kinds of the class of Panama, America, White Giant, etc. I make no claim that the list is complete or that it embraces every meritorious newcomer of recent years, for many which I consider are too expensive have been purposely omitted, and I have not tried, or even seen, nearly all. I will claim, however, that very few, if any, of those mentioned are likely to prove disappointing.

I will deal with the primulinus hybrids first, giving them in alphabetical order and indicating their colours and general characteristics as briefly as possible.

PRIMULINUS HYBRIDS.

The species Gladiolus primulinus (so called because of its yellow colour) is a pretty, small-flowered gladiolus, with its florets widely spaced on comparatively thin and wiry stems, which was discovered about twenty-one years ago growing near the Victoria Falls. Its upper petals are bent over like a hood instead of being wide open as in most other species. Crosses between the large-flowering varieties and the primulinus species and its hybrids have proved a veritable gold-mine to hybridists—not, perhaps, in a material sense, but on account of the wonderful colours and shades which have been released, colours not previously known in gladioli, not, indeed, in some instances, in any other flower. Primulinus hybrids, with their smaller blooms, wider spaced on thin and wiry stems, have a distinct advantage over the larger varieties for many forms of decoration indoors. They rival for daintiness such flowers as roses, sweet peas and carnations. I have heard more than one keen horticulturist predict that they will, in time, become more popular than any other type. I will not go quite as far as that, for my experience is that the average amateur gardener dearly loves a large flower, whether it be a rose, aster, sweet pea or gladiolus. I feel we are only just on the fringe, as it were, of the possibilities for improvement in the primulinus, and a few of the recent introductions make one very optimistic of their future. Should any reader—who may, perhaps, consider gladioli, as a class, too formal for his or her personal taste,have waded thus far through these notes, may I very strongly recommend a trial of these little-known primulinus hybrids. Here is a dainty subject, exquisite for decorative purposes, likely to please where its larger brethren fail to attract through sheer massiveness.

The early primulinus hybrids closely followed their small-flowered parent in size, form and placement. Now, some of the newer ones—particularly Americans—are much larger,

Digitized by Google

veering in general appearance round to the large-flowering gladioli. I sincerely hope raisers will concentrate on a type midway between, something which will combine daintiness and great decorative value with just that size of bloom which will show off their colours to the best advantage. But I am straying somewhat from the point, so will commence my list. I will divide the type into three sections for convenience only, terming them large, medium and small flowered. The small section would embrace such kinds as the well known Orange Brilliant; the medium, Maiden's Blush and the great majority of others; while the large-flowered are represented by the newer Alice Tiplady or Orange Queen.

ALICE TIPLADY (large).—Will become a great favourite. A soft orange saffron, almost a self colour, with first-class decorative qualities.

ATHALIA (medium).—Rather later in blooming than most primulinus, but one of the best, a good grower and a lovely colour. Bright orange salmon.

BUTTERBOY (medium).—Beautifully shaped blooms of clear butter yellow. A very pleasing variety.

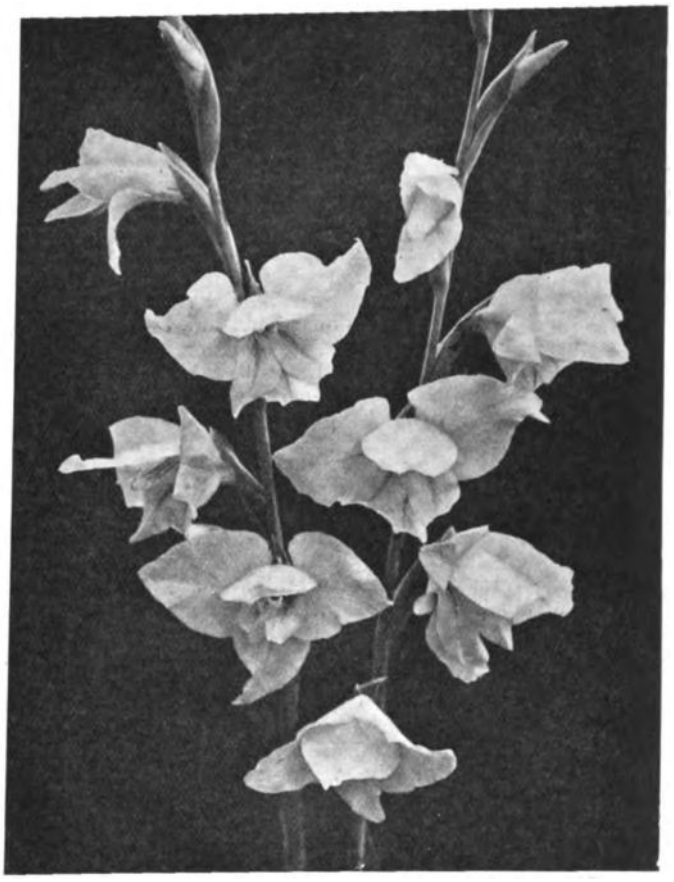
CITRONELLA (medium).—Lighter toned than Butterboy. A dainty spike giving a cooling impression. Clean and pure creamy yellow self.

DAPHNE (medium).—A wonderful dazzling vermilion, richer toned and better than the older variety Scarletta, which it will displace.

EURYDICE (medium).—This has been described as the best pink primulinus, but it has just too much carmine in its make-up to please my personal taste.

L'ECAILLON (medium).—A French introduction. A biscuity salmon with a distinct rose blotch. Very attractive.

L'INNOCENCE (medium).—A disappointment. It was said to be a pure white, but really contains too much cream to have



EURYDICE, A VERY FINE PINK PRIMULINUS.

any pretensions to this description. In my opinion, Citronella is far more pleasing and beautiful.

L'YSER (medium).—Another which originated in France. This will please most growers. It is very distinct and a good grower. Orange scarlet with yellow throat.

MING TOY (medium).—A deep buff self, very fine.

MYRA (large).—A very charming and delicately coloured American variety. Yellow ground, flushed salmon. Well worthy of a trial by all.

NYDIA (medium to small).—A lovely shade of salmon rose, but, in my opinion not a good type. Much of its beauty is lost through the flower stems being very thick in proportion to its size and placement.

ORANGE QUEEN (large).—A shade quite on its own in gladioli. A beautiful warm coppery orange. Sure to be much sought after, and one I can strongly recommend all to try.

ORIENTALE (medium).—This would be one of the best but for the tendency of its flower stems to grow crooked. Its colour is extremely pretty, lemon lightly flushed salmon rose.

ROSE LUISANTE (large).—Well worthy of a place in every collection. Beautiful rosy pink and a good grower.

SALMON BEAUTY (medium).—This is my favourite. Not only does it conform to my ideal size, shape and placement in primulinus hybrids, but its colour is exquisite, a most lovely salmon shade with yellow throat. The best advice I can tender is, whatever others you leave out of your collection, do not miss Salmon Beauty, probably the finest of them all to date.

SCARLET CARDINAL (medium).—Very early and the best scarlet self I have tried.

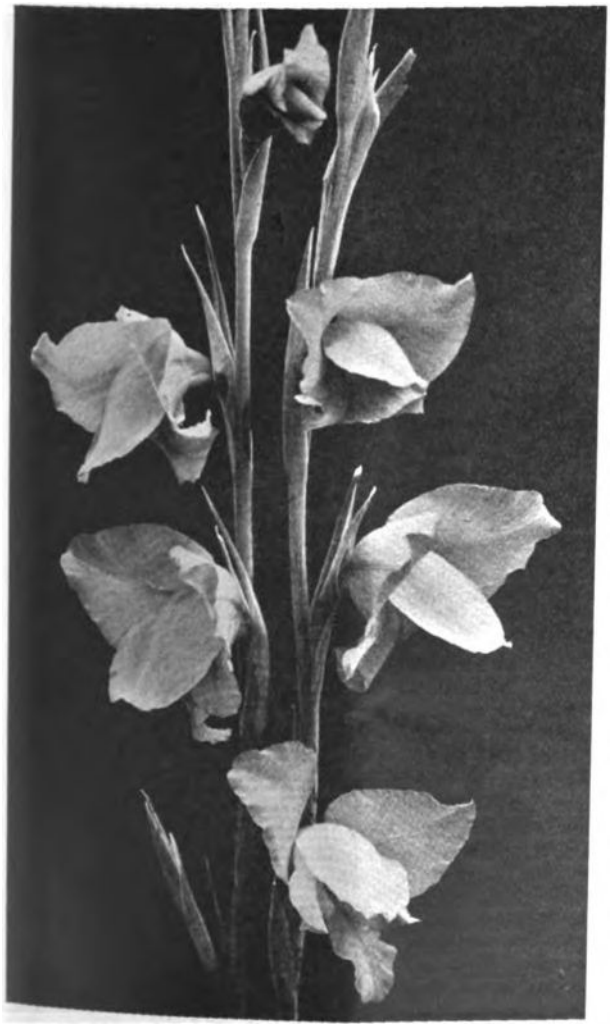
SHELL PINK (medium).—Very pretty. It is one of the best and cleanest of the pink primulinus.

SALMONEA (medium).—For decorations, this is one of the finest of the newer varieties. Salmon flushed glowing orange, very warm toned.

VERMILION SCARLET (medium).—Reminds one of the deep, rich, velvety, blood red of the wallflower. A deep velvety scarlet of great merit.

XANTHIA (medium).—A lovely gladiolus; an excellent grower, of a distinct shade of pure golden orange.

C. H. A. S.



DAPHNE, A RICH TONED VERMILION.

(To be continued.)

THE HISTORY OF GLADIOLI

THE SWORD LILY OR CORN FLAG.

BEFORE dealing with the origin of the garden race as we know it to-day, a brief glance at some of the species may prove interesting. The genus includes about a hundred and fifty species, of which some fifteen are natives of Europe and western Asia. The majority of the species, however, are to be found in South Africa, the headquarters of the genus. From time to time many of them have been in cultivation in our gardens, especially when the so-called Cape plants were so popular in this country. No fewer than fifty to sixty South African species are figured in the *Botanical Magazine*. In South Africa they are commonly known as painted ladies, pink and brown Africanders, Avondbloms and South African bluebells, the common names generally including a number of species. For example, the painted ladies include GG. blandus, debilis and other species, and the name is generally applied to species with pale pink flowers with darker markings. G. hirsutus is known as the large pink Africander, and G. recurvus as the blue Africander; while the yellow marsh Africander, G. tristis, is also known as the Avondblom, this name also being applied to other sweet-scented species that flower towards the evening. G. tristis and its variety concolor are still in cultivation.

The so-called bluebells include several species. G. Bolusii, commonly known as the Tulbagh bell; the Riversdale bluebell, G. Bolusii var. Burchelii; and G. spathaceus, the Caledon bluebell. These take their common name from the district in which they grow. The present-day garden race as we know it, descended originally from various South African species. It is divided into several sections, *viz.*, gandavensis, Lemoinei, Nanceianus, Childsii and primulinus.

The first definite records of a hybrid race refer to G. gandavensis. These hybrids were sent out by the well known nurseryman, Louis Van Houtte, in 1841, the stock being purchased from Mr. Bedinghaus, gardener to the Duke of Aremberg.

The parents of this race were given as G. oppositifolius (*Bot. Mag.*, t. 7292) and G. psittacinus (*Bot. Mag.*, t. 3032); on the other hand, some authorities give G. cardinalis (*Bot. Mag.*, t. 135) as one of the parents, while it is also stated that G. blandus (*Bot. Mag.*, t. 605) and G. ramosus were used. In any case, M. Souchet, a French grower, is said to have used these species and also G. pulcherrimus. Dean Herbert appears to have raised many hybrids, using such species as GG. cardinalis, blandus, carneus, inflatus, angustus and tristis; and in his "Amaryllidacea" he describes them as varying in colour from white, scarlet, rose, coppery to blackish purple. He also used GG. hirsutus, recurvus and versicolor, but describes their progeny as being somewhat tender in the open. The gandavensis race, with their large open flowers carried on straight rigid stems, proved very popular, and have continued more or less in favour up to the present day.

In 1878 another strain was placed on the market under the name of G. Lemoinei. They were raised by M. Lemoine of Nancy, France, who used the South African species G. purpureo-auratus (*Bot. Mag.*, t. 5944) as the seed parent, pollinated with some of the best varieties of gandavensis. The influence of the seed parent G. purpureo-auratus, with its roundish, yellow flowers with a purple blotch on the lower petals, is well marked in the hybrid race, which is also characterised by a strong constitution. In Holland a special strain known as Gelria has been selected. This strain is characterised by having flowers of beautiful blue, purple and mauve shades.

The Nanceianus hybrids were raised about 1889 by M. Lemoine of Nancy. Here again a South African species was used, *viz.*, G. Saundersii (*Bot. Mag.*, t. 5873)—a species with fiery red flowers with a white blotch on the lower petals, bordered with a band of minute white spots on a red ground. Crossed with the best Lemoinei varieties, a fine set of hybrids was obtained, in many ways resembling the seed parent G. Saundersii, in the marking of the petals, the large, more or less hooded upper petals, and the large individual flowers.

The Childsii hybrids were raised at Baden-Baden, Germany, by the late Max Leichtlin, as early as 1873. They originated from crossing G. Saundersii with good gandavensis varieties, and were named by the raiser G. Leichtlini. After passing through several hands these hybrids were obtained by the American firm of Childs, who renamed them G. Childsii and put them into commerce in 1892.

G. primulinus is the latest garden group in which a species has been used with the older garden groups. G. primulinus (*Bot. Mag.*, t. 8080) was first discovered in the Usagara Mountains in 1887, by Mr. J. T. Last, who sent corms to the Royal Botanic Gardens, Kew, in 1890. It was afterwards discovered in the "Rain Forest," opposite the Victoria Falls, by Mr. Francis Fox, the engineer of the bridge over the Zambesi. He reintroduced it into cultivation and flowered it in his garden at Wimbledon.

It is very surprising that this graceful and beautiful species was so long overlooked by the hybridist, for it was not until about 1914 that it attracted much attention. Since then, however, numerous varieties have been raised, the large-flowered varieties of the Lemoinei and Childsii races being used in the first instance for crossing.

There are still many beautiful species in South Africa, which, if introduced, should prove valuable for hybridising. Their introduction seems especially desirable when one considers what has resulted from the use of G. primulinus. It would be an undoubted advantage if some of the sweet-scented species could be used, for up to the present the hybrids are devoid of scent.

In Canada and the United States of America the cult of the gladiolus is very popular, and many fine varieties have been raised, some of the newer sorts being listed at $25 and $75 per corm.

J. C.

GLADIOLUS CULTURE

BOTH in summer and right on to the last days of autumn, the gorgeous spikes of the brilliant gladiolus form one of the most vivid colour pictures which the hardy flower garden can produce. Every imaginable shade—and delicacy of shade, too—is represented, and a single flower will reveal a wealth of beauty that is entirely unsuspected.

Embed half a dozen corms of that old-fashioned form, brenchleyensis, in the damp brown earth round a tuft of pyrethrum in March, and then, after the latter has provided its wealth of daisy flowers in early summer, the distinctive sword-like foliage of the gladiolus will spear its way upwards and August will see a blazing mass of fiery scarlet spikes that completely obliterate the green effect of the pyrethrum leaves. By planting a little earlier or later, too, one can vary the period of flowering of the same variety: although, on this score, there is a wide season covered by naturally early, mid-season and late varieties.

There is no soil that will not grow these handsome flowers to perfection—or, rather, no soil which, by a little cultivation, cannot be made to do so. A rich, deep, sandy loam is the best of all: so that, where the soil is heavy, it will be necessary at planting time to surround each corm with plenty of sharp sand, a precaution which prevents stagnant moisture from lodging round and rotting them. In all cases the ground must be deeply dug and heavily manured during the winter, cow manure being especially valuable where the soil is light and thin. Do not make the mistake of manuring at planting time; the fumes given off by rank manure will soon cause disease in the corms. Since the growth is directly upright, corms may be planted fairly close together, 4ins. apart being about right, unless other plants are growing between them. It will be noted that different varieties vary greatly in the size of their corms, and so call to be planted at different depths, a point that should not be lost sight of when a number of varieties are being grouped together. Do not plant too shallowly, however, as, by deeper planting, the risk of the plants being snapped or broken by high winds in autumn is greatly minimised.

As distinct from their use in mixed borders, the gladioli are capable of superb effects when used in beds of one or more varieties together. In this case, they should be planted 6ins. to 8ins. apart and the ground carpeted with a dwarf annual of suitable colour. A very pretty effect may be secured along the lines of a three

Digitized by Google

tier bed. Thus, the annuals would cover the ground, then single bulbs, evenly spaced, of montbretia would flower at about 18ins. above this, with the gladiolus at 2½ft. to 3ft. In planning out beds of this kind, you can provide for continuity of bloom by planting three batches of corms, at intervals of about three weeks, which will give at least two months' unbroken display—no small achievement when one considers how little demand they make upon our time. If the soil is very light, it is a capital plan to mulch the bed heavily with rotted leaves, as these assist considerably in keeping the soil moist; while, on any soil, free supplies of water must be given when the weather is dry.

To ensure the finest possible spikes for exhibition work, special culture must be given. Not only must the ground be thoroughly prepared, but the best varieties should be chosen; varieties that will give you large flowers and which are known to expand several blooms at once. Directly the spike can be seen or felt within the sheath, begin to feed regularly with liquid manure, taking care to vary this as much as possible and always to use it very weak.

Each spike should be encased in a special frame, consisting of three sides made of wood, with a sliding glass front. The whole of this should be supported by a firm, strong stake and be placed over the spike at an early stage of its development. The object is to shade the lower half of the spike until the upper part has made progress, and, to this end, the lower part of the glass should be well screened by whitewash or some other shading material, so as to retard the opening of the lower flowers until the upper ones are beginning to expand. Do not remove the shading too soon. Gladioli can be raised from seed. Sow in shallow boxes, in gentle heat under glass, and plant out later; but where this cannot be done, the sowings may be made in the open ground early in April. Draw the drills rather shallowly, and cover the seeds but lightly with soil; then take care to keep the soil evenly moist. During the first summer they will only make a mass of short, grass-like growth, and when this has withered in autumn, lift the cormlets and store in a frost-proof place.

The following spring, plant out again, about 1½ins. deep, giving a little more space. Much more top growth will be made, and, when you lift at the end of the season, quite good-sized corms should have been made. The following spring, plant again; but this time allow the full 4ins. from corm to corm. B.

THE VALUE OF MONTBRETIAS

THE plants generally known in gardens as montbretias are more correctly called tritonias. Of these, botanically, there are two sections. One includes T. crocata, the many beautiful varieties of which deserve to be more generally grown for greenhouse decoration; the other, the plants under consideration, *viz.*, tritonia (montbretia). The original species of tritonia are natives of South Africa, and the garden race as we know it to-day first originated as a bi-generic cross between T. Pottsii and the closely related Crocosmia aurea, (syn. Tritonia aurea). T. Pottsii was introduced to the Edinburgh Botanic Garden in 1877 by Mr. G. H. Potts, and in 1883 was figured in the *Botanical Magazine*, t. 6722. Crocosmia aurea was introduced during 1846, and is figured in the *Botanical Magazine*, t. 4335.

In this country, the initial start to the many fine present-day varieties was given by Mr. George Davison of Westwick, who raised many good varieties. His first success was George Davison, a fine yellow, while others of his raising were Westwick, Star of the East, King Edmund and Lady Hamilton. His splendid work was carried on by the late Sidney Earle of Earlham, who raised such fine varieties as Nimbus, Lemon Queen, His Majesty, Queen Elizabeth, Queen Alexandra and Henry VIII.

Montbretias may be had in flower during August, September and October, when, if properly cultivated, they make a wonderful show in beds and borders. Too often, however, their cultivation is more or less neglected and they are allowed to grow into a crowded mass, with the result that their inflorescences and flowers are small and poor. In the cut state they are unrivalled for house and table decoration, opening their flowers in succession for at least ten to fourteen days.

In the colder parts of the country they may be regarded as somewhat tender, and where this is so they should be protected by some loose litter, or the corms may be lifted and stored dry for the winter. Otherwise the plants may be lifted and stored in a cold frame. Later on I shall refer to this method of wintering them.

In the milder parts of the country where the soil and climate suit them—the older varieties, at least, increase very rapidly and, if not restricted, soon overrun all the smaller plants in a herbaceous border. In Wigtownshire I have seen them growing in the grass on the embankments by the railway stations.

As regards their cultivation, they naturally do best in a warm, fairly light and well drained soil, which should be thoroughly cultivated and enriched with plenty of well decayed farmyard manure and a dusting of bone-meal. Before planting, a sprinkling of lime should be lightly forked in on the surface of the bed. In the ordinary way, montbretias should be replanted every second year, otherwise they get overcrowded. Most writers advise replanting during the autumn; this I consider most unwise, except under very favoured conditions, and it certainly should not be attempted with new and scarce varieties. It is wiser to wait until spring, when they are starting into growth, when they may be lifted and divided into small pieces, replanting them about 1ft. apart either way.

Where they are lifted towards the end of October and the corms stored dry for the winter, they may safely be planted towards the end of March, or the corms may be potted up or placed in boxes and started into growth in a cold frame. When hardened off they may be transferred to their flowering quarters towards the end of April. The foregoing remarks

GROUPS OF ONE OF THE MODERN VARIETIES OF MONTBRETIA LOOK WELL IN THE BORDER.

apply where just ordinary results and quantities of flower are aimed at.

Where the best results are required, and flowers up to exhibition standard necessary, a somewhat different procedure must be adopted. Towards the end of October the plants should be carefully lifted with a fork, taking care not to injure the stolons. Place the plants carefully in boxes, working a light sandy compost carefully in among the stolons. During the winter they should be stored in a cold frame, keeping them on the dry side at the root. About the middle of February they will have made growth about 3ins. long, and the stolons, rooted by this time, should be detached separately and planted several inches apart in boxes, or placed singly in pots where small quantities are being dealt with. Grown perfectly cool and carefully hardened off, they should be planted out in their flowering quarters towards the end of April or beginning of May, placing them from 9ins. to 12ins. apart. By this method the corms are not used for planting, only the rooted stolons. Each plant usually only produces one flowering shoot, which, however, with most varieties may be from 3ft. to 4ft. in height. During the earlier stages the beds should be kept well stirred with the hoe; but later on in the season, when the stolons begin to run, care must be taken not to injure them. Usually they stand dry weather very well, but during prolonged dry spells it may be necessary to water them. Under such conditions a light mulch of decayed stable manure or leaves may be applied with advantage. Generally, no staking is required, as they are rigid and self-supporting. They are easily raised from seed, but for seed production must be grown indoors in a cool greenhouse. Montbretias have reached such perfection now that only the finest varieties should be used for this purpose. Tritonia rosea (*Botanical Magazine*, t. 9280) is a slender-growing species with small rosy red flowers, and is hardy in warm situations in the more favoured parts of the country. So far as I am aware, this species has never been used for hybridising, and should be valuable for this purpose. J. COUTTS.

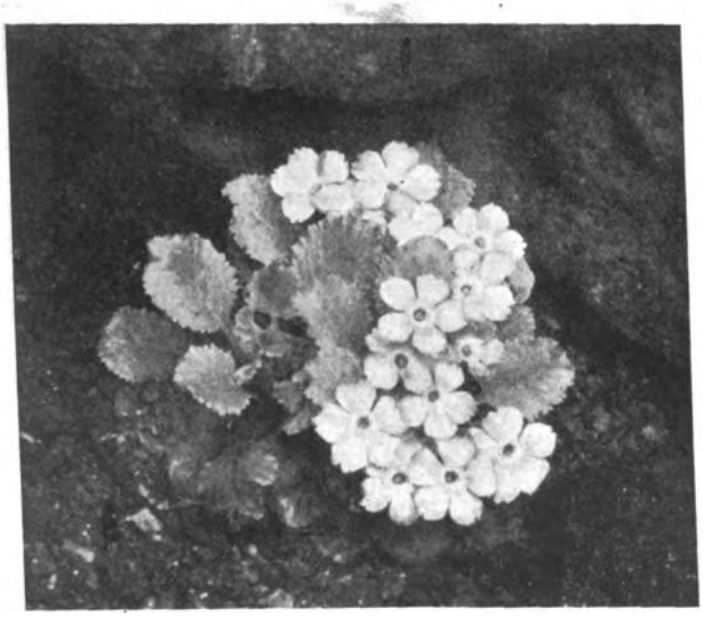
PRIMULAS FOR THE GARDEN

BY JOHN MACWATT.

(*Continued from page* 134.)

SECTION NIVALIS.

IN this section PRIMULA CHIONANTHA promises to become a popular garden plant, as it is not only beautiful to look at, but also hardy and robust in habit. I have seen it growing and flowering to great perfection on the open rockery of Miss Brown at Longformacus, in one of



A FINE PLANT OF P. WINTERI UNDER AN OVERHANGING ROCK.

the coldest situations of the Lammermoors. The rockery was protected from the sun and wind by a wood. Here I also saw P. Reidii growing and flowering in the open. P. chionantha, which flowers in May, has long, leathery leaves about 12ins. long, the under sides of which, with the stem, pedicels and calyx are covered with a bright golden meal. The stout stems, 12ins. to 20ins. in height, bear whorls of lovely fragrant, ivory-white flowers, each about an inch across. It was collected by Forrest on the open alpine meadows of the mountains of Chungtien at a height of 12,000ft. to 13,000ft.

P. SINO-PURPUREA, another of Forrest's collecting on open moist pastures in Yunnan, has dark green leaves, about a foot in length, the under surface being covered with golden meal. The flower stalks and pedicels are also farinose. The flower stem, in length from 12ins. to 24ins., bears an umbel of fine fragrant purple flowers, the eye of which is greyish white. The calyces are brownish purple. This should be a noble plant when it can be well grown. Unfortunately with me it has not proved hardy and the few plants I had all died. It was shown by me at the Chelsea Spring Show, May, 1924, and a good picture of it appeared in THE GARDEN, May 31st, 1924.

P. SINO-PLANTAGINEA has narrower leaves than P. sino-purpurea, farina not so deeply coloured, but the flowers are deeper in colour. It was well figured in THE GARDEN, May 31st, 1924.

P. PARRYI comes from the Rocky Mountains. In its native home it is found in wet ground and is reputed to be a difficult plant to cultivate in this country, but I find it otherwise, as it does well with me in a rich rose border, where it does not get the direct rays of the sun. Here it flourishes. Why this fine plant should be difficult to keep I cannot understand, as it must be hardy, seeing it grows along the margins of brooks near the snow line in the Rocky Mountains. It has erect leaves and stems a foot high, bearing good-sized trusses of crimson flowers with a yellow eye.

SECTION MALACOIDES.

P. MALACOIDES is too well known to call for much detail. The typical plant has lilac flowers, but numerous varieties have been offered recently, with fine colours, including good whites. It is almost hardy and the writer has seen plants which had stood the winter without protection in a sheltered position in south-eastern Scotland.

P. FORBESII is a pretty primula from the rice fields of China and Burma. It is not quite hardy in cold districts and is best in a greenhouse. The original introduction was an annual plant, but that now grown is perennial. It is possible that the annual and perennial forms are distinct species, but may only be microforms of P. malacoides. I have grown a great many plants of P. Forbesii and generally get some with flowers of a lilac colour, much like P. malacoides and others of a good ruby colour.

SECTION SUFFRUTICOSA.

P. FORRESTII, collected by Forrest in Yunnan was introduced to cultivation in 1908 by Bees, Limited. Few hardy primulas attracted more attention than P. Forrestii on its introduction. Its sub-shrubby character led one to hope that it would be a success grown in the open. Unfortunately it has been rather a disappointing plant, damp rather than cold being its chief enemy. If planted outside it should be in a crevice of almost perpendicular rock, with a shady exposure. In this position I saw several plants growing luxuriously in Mr. Hanbury's rockery at Brockhurst, East Grinstead. It grows in limestone cliffs, where its fine green leaves are highly attractive on the great tufts it forms there. The flowers are deep yellow and very fragrant.

P. RUFA, I notice, is catalogued by a number of nurserymen, but I question very much if they have the correct plant, as I have bought a number and all have turned out to be P. Forrestii. P. rufa differs from P. Forrestii in that it has reddish hairs on the leaves and is of stronger habit and the whole plant is mealy. The flowers of P. rufa, when in bud, are sulphury

Digitized by Google

white and a pale yellow when opening, which is quite distinct from P. Forrestii. Anyone unacquainted with P. rufa on first seeing it in the bud state, would say it was a white Forrestii. P. rufa appears to be almost out of cultivation. I showed it some years ago at Chelsea, but have never seen it since and will be most grateful if any reader can tell me where I can procure a plant.

SECTION INVOLUCRATA AND ITS ALLIES.

P. INVOLUCRATA grows mostly in water in its native habitats in the Himalayas. This is one of the easiest and hardiest of primulas to grow. It forms small stalked leaves, almost close to the ground and slender stems from 6ins. to 12ins. in height, with umbels of white flowers, borne early in the year.

P. WARDII is practically the west China form of P. involucrata, from which it differs by its colour. It has light mauve coloured flowers and is very hardy and robust.

P. SIBIRICA is the western representative of P. involucrata and equally good in gardens. The flowers are rose or bluish. The seeds of this primula were collected by Wilson. P. sibirica is exactly equivalent to P. Wardii and it is not possible to keep them as distinct things.

The above three species are all in a series. All have the bracts prolonged deeply below the insertion.

P. CHRYSOPA, a tufted, marsh-loving perennial, found by Forrest in Yunnan growing in strong, moist alpine pasture. Although hardy it is more beautiful when grown under glass, as the meal does not get washed off by rain. The fragrant flowers are of fine lilac colour with an orange eye. It differs from P. Wardii, which it resembles in habit, by being farinose and by having no spurs to the bracts.

P. CONSPERSA has stems about a foot high, bearing whorls of pale lilac flowers above rosettes of petiolate leaves, which are mealy on the under surface. It is a native of Kansu, where it was found by Purdom growing in damp soils at an elevation of 8,000ft. to 9,000ft.

SECTION AURICULATA.

P. TIBETICA has been well figured several times and as far back as 1918 was illustrated in THE GARDEN of July 20th, from the photograph of a plant I had flowering in a cold house. It is a small plant with flowers of a pretty shade of pink, with a yellow eye and with meal on the under side of the leaves—a feature which has been doubted—but the illustration referred to shows the farina quite distinctly. It is said to have been discovered in western Tibet many years ago by Strachy and Winterbottom, and was also found by Sir Joseph Hooker in that part of Tibet north of Sikkim. It reaches a higher altitude than P. sikkimensis and is subject to six or seven months of the most severe weather and covered with snow, which does not thaw off the ground until the end of May.

SECTION SOULIEI.

P. RUPICOLA grows from 3ins. to 8ins. in height and the flowers are described as rose with a yellow eye. P. rupicola comes from Yunnan, where it grows on boulders and stony pastures at an altitude of 12,000ft. It is one of the very mealy primulas.

SECTION CANDELABRA.

P. GLYCOSMA is very like P. Poissonii, but has strongly scented leaves. The flowers are velvety crimson with a

P. BURMANICA is the Burmese equivalent of and has good claims to be considered quite a dis The flowers are red-purple. It was found by Ki in Upper Burma.

P. HELODOXA is one of the best of our recent primulas and may be foun localities in Yunnan at from 5,000ft. to 6,000ft., a Burma at a height of 8,0 of the plant is covered farina and the scapes sometimes 2ft. or 3ft. several whorls of numer yellow pendent flowers. I marshy land or in a cool, border and is hardy.

P. SMITHIANA may be the Himalayan form of which it much resembles, b flowers of P. Smithiana are with green, a feature a helodoxa. In P. helodoxa i more reflexed, the corolla and the flowers of a de P. helodoxa is a much stro

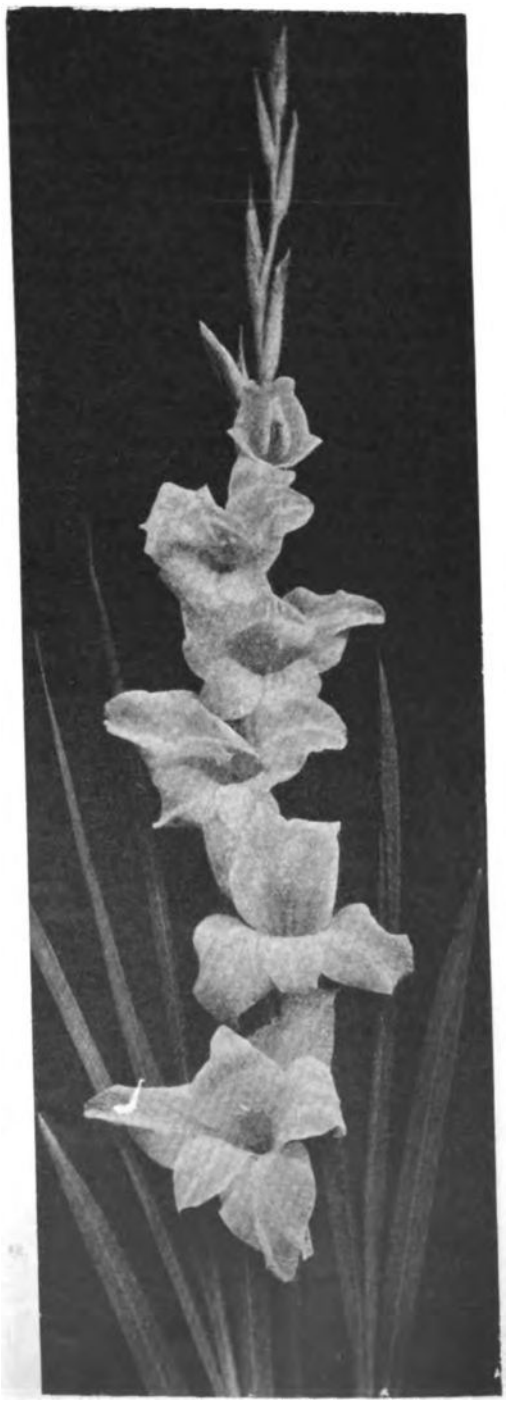
WHAT TO AIM

There is little doubt that the
kinds has come to stay. If in t
comparatively few gardens, it
near future it will take its pl
sweet pea as a flower that



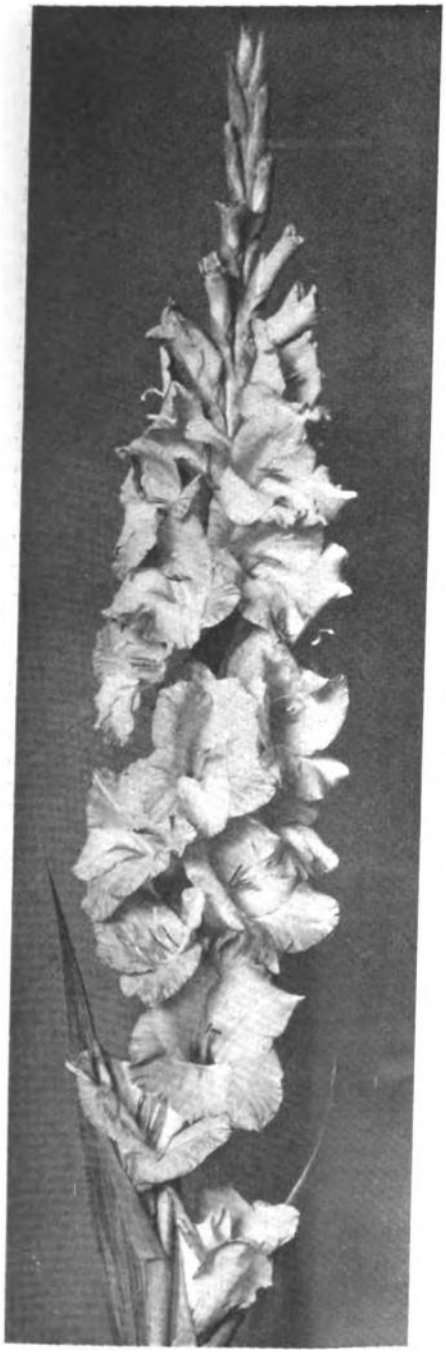
MORE OPEN IN FORMATION.

PERHAPS some readers of THE GARDEN *who have not yet realised all the possibilities of gladioli will look at this page. It should be sufficient to say that Gladioli are pre-eminent in four qualities—ease of culture, good colour, upstanding growth, and the lasting quality of their handsome multi-flowered spikes, so excellent for house decoration. Among large-flowered varieties one may choose: pinks—Pink Perfection, Byron L. Smith, Marechal Foch, America; blues and lavenders—Rev. Ewbank, Baron Joseph Hulot; yellows, etc.—Loveliness, Flora, Golden Measure; white—White Giant; scarlets—Isis and Red Emperor.*

Digitized by Google

AT IN GLADIOLI

the popularity of Gladioli of all in the past it has been a flower for it is safe to prophesy that in the place with the daffodil and the at will be seen in every garden.



CLOSE SET SPIKES.

A LATER introduction than the large-flowered type is the primulinus hybrid, originating from the inclusion of G. primulinus as a seed parent. In primulinus hybrids the large-flowered spike has given place to a more graceful setting of hooded flowers on the stem, thus producing varieties which, although smaller in flower, have every appearance of elegance. No one can go wrong if they include some of the following primulinus hybrids: yellow and orange—Souvenir, Niobe, Psyche and Alice Tiplady; pinks and salmons—Hermione, Laetitia, Salmon Beauty, Maiden's Blush; scarlets—Firefly, Woodcote and Adonis.

NOTES OF THE WEEK

PIRÆA AITCHISONII.

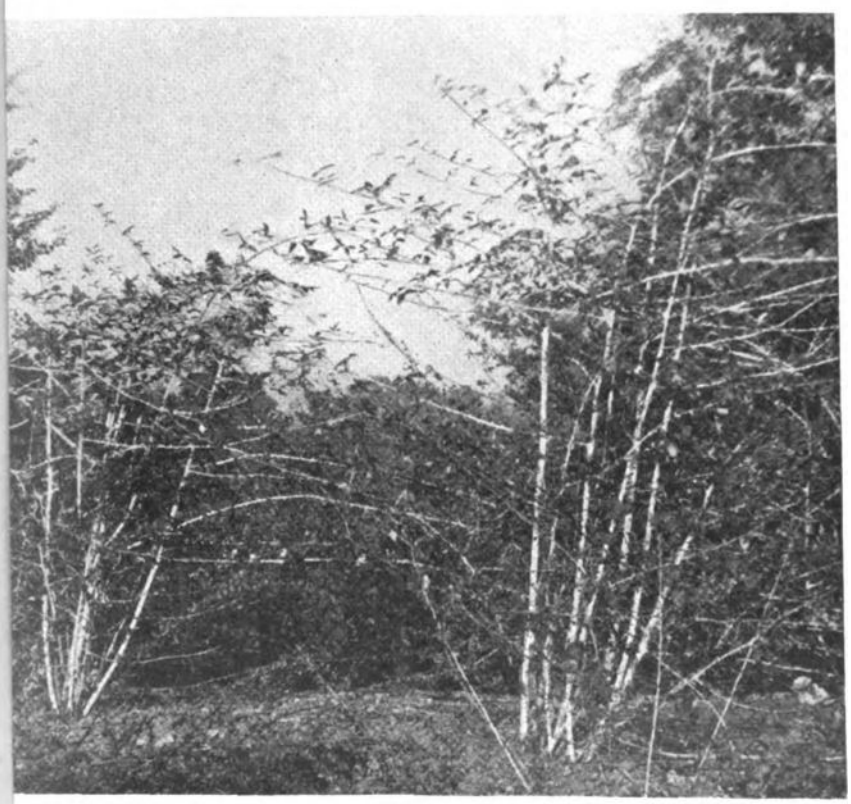
Y spiræas afford us many lovely for the adornment of our gardens nt us with a wonderful choice of d things. They vary greatly in and one of the most distinct is s, which one still sees far too ere shrubs such as this are generally I call it a "shrub," and as such ally grown; but in a garden which il a few years ago I had a plant of onii which was at least 12ft. high nore the aspect of a tree than of a was growing near the base of a poplar and, despite the drain resources made by the proximity plar, it grew rapidly after planting. irst two or three years it did not d was coming to be looked upon as erer of the ground," although its e, of the true pinnate type, was tself. Then it began to flower, and ate summer and autumn big flat of creamy white flowers which, on ng stems of the "shrub," were ly fine. For suitable positions in n this native of Afghanistan and of India is to be recommended. ness is beyond reproach, and its t and attractiveness entitle it to a tion in the estimation of lovers of flowering habit. Planting may be time during early spring.—S. A.

ME JAPANESE IRISES.

new varieties of the Japanese or mpferi iris have been introduced rom Japan and most of them seem xceedingly well when discreetly n a moist but not too cold place. ately we have to rely on "mixed s" from most of our home nursery-seedsmen, but it must not be over-at the houses with a direct Japanese connection stock the named Japanese sorts. These I do not pretend to know well, but I have a few good ones which are well worth mentioning, on account of their fine flowers and delightful colours. I hope the names are correct—but I can tell readers where to go and get them, and other varieties if they wish. Kasumi, almost pure white; Nisiki-yama, edged with rosy carmine; Fuka-murasaki, velvet purple; Sasa-nami, blue and purple; Sakura-gawa, a peculiar pale lavender; Kongo-san, dark blue edged deeper blue; Akafurin, red and white; Yurushi-iro, velvet red. Cost soon calls a halt when purchasing these really gorgeous plants, for they are expensive—but really they are worth it.—CLYDESDALE.

RUBUS BIFLORUS.

WHILE several of the numerous species of rubus are desirable on account of their floral beauty, others are well worth growing for the beauty of their stems, which prove very effective during the winter season. Of the latter group Rubus biflorus is one of the most attractive. This species, which is popularly known as the whitewashed bramble, is an introduction of long standing from the Himalaya and has proved itself to be quite hardy in this country, withstanding the severest frosts. It is a vigorous grower, sending up stout canes up to 10ft. in height, from near the top of which spread other stout shoots which are sparsely clothed with leaves. These are variable in size and shape, having usually three or more lobes, their upper surfaces being downy and pale green in colour and the lower almost white. The stems are armed with stout prickles and are completely covered with a thick, waxy covering, which persists throughout the winter, giving to the growths the appearance of having been whitewashed. Flowers are produced either at the ends of the lateral shoots or in the axils of the leaves, are white and about ¾in. in diameter, but are not very attractive. They are followed by edible, golden yellow fruits, similar in shape to those of the cultivated raspberry. A variety of this species, the recently introduced R. biflorus quinqueflorus, has larger flower clusters, which are not unattractive and is therefore preferable to the type, being similar in all other respects. Though perhaps rather too coarse for growing in a shrub border, R. biflorus is very effective if planted in grassland against a background of conifers or other evergreens, when the whiteness of its stems will be seen to advantage. It likes an open sunny situation and being of a vigorous nature should be planted in deeply worked, loamy soil. Pruning consists of the removal of the fruited canes and any weak shoots during August, their timely removal allowing the development of the present season's growths. The propagation of this species is a simple matter as it produces occasional suckers which may be removed if required, while its seeds will be found to germinate freely and soon produce strong plants.—A. G. F.



THE WHITEWASHED STEMS OF RUBUS BIFLORUS.

CYPELLAS.

IT is a good many years ago since I first made the acquaintance, through a spring-planting bulb list, of Cypella Herberti, and this plant has been a source of much pleasure and interest ever since. A bulbous subject related to the irises, C. Herberti seems to have been introduced from its native Buenos Aires just one hundred years ago, but it has never been common as an outdoor subject, probably owing to the fact that it is usually bracketed with the tigridias, ixias and other half-hardy bulbous subjects, which are not a success everywhere. But I find that in the light loam of a sunny border, C. Herberti is as permanent as most things and, unlike the majority of its relations of the kinds mentioned, it flowers with the most commendable regularity every summer.

C. Herberti grows to about 2ft., the broad, grassy leafage is sparse and the quaint flowers, with a pretty twist at the base of each of the three "falls," are a curious bronzy-buff tint. C. platensis is another species which we grow under similar conditions. It is rather taller than the foregoing and the flowers, pale yellow and white in the cup, have "falls" of a clear blue—a very lovely combination.

In places where these plants are hardly likely to survive the winter the bulbs can always be taken up in autumn and kept indoors until spring. But they are extraordinarily hardy in light, freely drained soil. We have just had severe frosts covering several weeks, over 20 degrees on several nights, but I find that the cypella bulbs are quite sound and they are not deep rooters.—A. T. J.

SOME BOG-LOVING SHRUBS FROM CANADA.

HAVING recently seen these shrubs growing luxuriously in their natural homes, one wonders why they are so rarely seen in our gardens. Admittedly a few are difficult to get established, others are of easy culture and are well worth growing. Ledum grœnlandicum, commonly called the woolly Labrador tea, is a dwarf shrub of about 4ft., with clusters of white blossoms and foliage of a pale green colour, with a woolly-like reverse, which often turns a curious rusty colour. This shrub is proving a slow grower here. Ledum glandulosum is a smooth form of the above.

Chamædaphne calyculata, the dwarf cassandra, is another interesting shrub, 3ft. in height, foliage of a dull green, which sometimes gets a trifle bronzed. Its flowers are white and fragrant, and appear earlier

Digitized by Google

than is the case with ledum. The cassandra has proved a good plant to grow.

Then there are the laurels, Kalmia angustifolia, commonly called the sheep laurel, a charming shrub in every way. Its flowers are in clusters, of a crimson colour fading to pink. It should be planted in sandy peat and in full sun by the waterside. It is a shrub that has much to recommend it. K. polifolia, the swamp laurel, has very narrow foliage with a silver green reverse, which is quite an attraction. Its flowers are of a delightful pink. We collected it at a fairly high altitude by a running stream. This kalmia seems easy to establish, and is very pleasant associated with K. angustifolia. Rhodora canadensis is another shrub growing well here, but it is not evergreen like the kalmias and kalmias, its small pink flowers opening before its leaves. It seems of easy culture if given a moist situation.—R. MOORE, *Thorpe Hall.*

SOME NOTABLE GARDEN CLEMATIS.

AMONG hardy flowering creepers, it would scarcely be possible to point to one that has enjoyed a greater popularity than the clematis. It is ubiquitous, from the fact that it is grown from John o' Groats to Land's End. You meet it clothing pergola and arch, covering veranda and porch with its rich clusters of blossoms, making more attractive the fronts of villa residences in the suburbs, and transforming cottage gardens into places of delight. Perhaps in the various sections of the genus no two are more largely grown than the Jackmanni and lanuginosa, and, practically speaking, they can be planted at almost any season of the year, being always procurable in pots. No time, however, is better than spring for moving them to new quarters, and, having regard to their permanency, it is worth while to consider their requirements and to furnish them with soil in which they will thrive. In planting, it is desirable to dig sufficiently deep to admit of drainage being provided. Two feet should be the minimum, three is better, as it affords ample room for brickbats before filling in with loam, old mortar rubble and cow manure. It is well, too, at the time of planting, to fix some kind of support to admit of the young shoots to be tied, until they are able to "fend for themselves."

In the Jackmanni section, no variety has had more patronage than the one bearing that name, whose rich purplish clusters are so frequently seen in early autumn, but Jackmanni superba gives us much superior flowers, with no diminution of quantity.

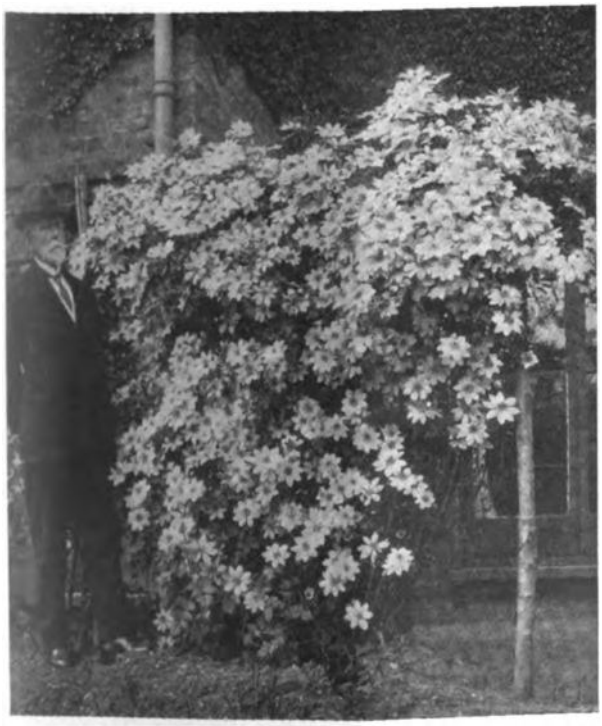
Other members of the Jackmanni group deserving of special mention are:

COMTESSE DE BOUCHARD, rich pink.
MAGNIFICA, reddish purple, red bars.
SNOW WHITE JACKMANNI.
MME. EDOUARD ANDRE, bright velvety red.
PRINCE OF WALES, pucy purple.
BARON VEILLARD, lilac rose.

There are many in the lanuginosa section worthy of special commendation. They are noted for their large handsome flowers, as well as their prodigality. The following have proved themselves, and, once established, contribute much beauty to a garden.

NELLIE MOSER, light mauve, red bars.
ROBERT HANBURY, bluish lilac, edged with red.
FAIRY QUEEN, flesh, pink bars.
HENRYI, creamy white.
BEAUTY OF WORCESTER, bluish violet, white stamens.
LILACINA FLORIBUNDA, pale lilac.

It not infrequently happens that those who take up the culture of clematis for the first time and select their plants from the Jackmanni and lanuginosa groups, fall into a common error in regard to pruning. Those in the first-named section should be pruned in February or March to a foot or so of the base, as they give the finest blossoms on new wood. Those in the lanuginosa section do not need so radical a treatment, a shortening of the shoots after flowering sufficing.—W. LINDERS LEA.



A FINE PLANT OF CLEMATIS NELLIE MOSER.

TAN IN THE GARDEN.

I SOMETIMES notice that in districts where tan can be readily procured it is brought into use for the making up of hotbeds in spring, and for spreading on garden paths. My one and only experience of it for fermenting did not encourage me to try it a second time, as I found that the heat was not maintained as in the case of stable manure; indeed, it quickly cooled, and the tan itself was a happy hunting ground for many pests which it attracted. It was a long time before I could eradicate them, and at the finish the tan had to be dug into the ground to get rid of it, a mistake which I afterwards regretted. In a town near to where I live, tan used to be easily procurable, years ago, and utilised by cucumber growers for a time. I suspect it was given up because of woodlice which followed it. For paths, it is a cheap makeshift; but when decay has once set in it is anything but pleasant to walk upon. —W. FOWKES.

THE CORK FIR.

A VERY beautiful, but little known, fir is Abies arizonica, usually regarded as a variety of Nuttall's A. lasiocarpa (the A. subalpina of Engelmann), widespread in western North America from Alaska southward along the Rocky Mountains. The Arizona fir is a slender tree from 45ft. to 65ft. tall and is remarkable for its thick, greyish white, corky bark, which is in evidence

THE CORK FIR, ABIES ARIZONICA.

on quite young plants. The leaves are pectinately arranged with the upper ones directed forward. The upper surface is more or less grey-green and conspicuous bluish white stripes mark the lower surface. The branching is dense, the leaves abundant and the prominent under surfaces give a delightful bluish grey appearance to the whole plant. In the Hunnewell Pinetum at Wellesley, Mass., there is a singularly handsome specimen of this fir planted when about 4ft. high in 1912 and now 16ft. tall.

The cork fir was introduced into Europe in 1901. According to Bean it came to England in 1903, but gives no promise of thriving there. It is to be hoped that this prophecy proves false, since this fir is more than ordinarily rich in garden merit. It is essentially a subject for trial in those parts of the British Isles, where greatest extremes of climate prevail. In smoke-free parts of the Midlands and the easterly parts of England from the Thames estuary north, there are many gardens in which this fir would probably flourish.—E. H. WILSON, *Arnold Arboretum.*

THE WINTER ACONITE.

THIS plant has a charm of its own. The colour, for one thing, is unique among hardy border plants flowering in January. It is a member of the buttercup family and, if seen in any out-of-the-way place, might be mistaken for a ranunculus.

Its early-flowering habit is well known, and like the crocus, on bright days it opens wide. The flower lasts for over four weeks—quite a long time—and a large quantity of seed is produced. On one stem I have counted as many as nine seed vessels, each containing on an average six seeds, making a total of fifty-six. The winter aconite is a native of central and southern Europe, and is found "in moist shady places, and on hills." It is a pleasant plant to have in the garden, and along the front of the herbaceous borders it is excellent.—DAVID ARMSTRONG.

CORRESPONDENCE

ROSE ZEPHIRINE DROUHIN.

SIR,—I was very glad to see the letter from Mrs. E. H. Palmer in THE GARDEN for February 20th on this rose, for, like her, I think it is the best all-round rose to grow, and wonder why it is so seldom seen. I can endorse all Mrs. Palmer says about its good qualities—colour, scent, absence of thorns, ease of cultivation, etc. To judge from catalogue descriptions, this rose would seem hardly worth considering compared to new productions, which are depicted in such sledge-hammer superlatives, yet, for those who want a really good garden rose rather than a few exhibition specimens, the very reverse is the case. One reason only can I suggest for its scarcity; in those few places where I have come across it I have generally found that it has been pruned like a bush rose instead of a climber, with the natural consequence that few blossoms are produced. Why it should be maltreated in this way is a mystery, but, if it is at all general, it may account for the neglect of this most beautiful pink, sweet-scented rose.—F. H. HUTTON, *Lincoln*.

SIR,—Mrs. Palmer's letter *re* the Rose Zéphirine Drouhin is of much interest to me. I have grown it for years as a bush rose, and it has never failed me, whether the summer has been wet or dry. It has a most delicious scent, which, unfortunately, seems a lost art with roses nowadays. Its colour never alters, and I have been able to mix freshly gathered Zéphirine Drouhins in the same vase with others that have been in the house for days. Of how many roses can one say that? One of the most beautiful sights I have ever seen was a hedge of it when in full bloom.—M. NEILSON, *Ayrshire*.

ROSES UNDER GLASS.

SIR,—I was much interested in the note on "Roses Under Glass," by Mr. William Grant, Kincardineshire (page 120, February 20th). I am pleased to comply with his suggestion that I should give a selection of roses suitable for a rose house artificially heated. It is not a wise plan to grow many varieties unless the structure is a large one. A medium-sized house should contain the following: Elsie Beckwith, rich pink; General McArthur, brilliant crimson; Hugh Dickson, deep red; Mrs. G. Norwood, bright rich pink; Mme. Butterfly, an improved Ophelia; Premier, deep pink, very sweet; Ulrich Brunner, cherry crimson; Caroline Testout, bright rose; Charles E. Shea, rose pink; Lady Hillingdon, apricot yellow; Lady Pirrie, coppery red; Margaret D. Hamill, straw tinted orange; Mme. A. Chatenay, carmine pink; Mrs. H. Stevens, white, long buds; Mrs. George Shawyer, brilliant rose; Richmond, scarlet-red; Sunburst, carmine-yellow; Hadley, bright red, very fragrant. Princess Mertchersky, clear pink, does not fade in heat. Molly Sharman Crawford, white, large well shaped buds on strong stems. I have named several hybrid perpetuals in this list because I have them in my own houses and find them excellent.

If there is only room for six varieties in a greenhouse, then I should recommend the following: Mrs. H. Stevens, Molly Sharman Crawford, Mme. Abel Chatenay, Lady Hillingdon, Mme. Butterfly and Richmond. Two whites are named because they cannot be dispensed with. Some cultivators may like to cover a trellis. For this purpose Caroline Testout, Mrs. H. Stevens, Molly Sharman Crawford, Mme. Abel Chatenay, Richmond, Mrs. G. Shawyer and Climbing Mme. E. Herriot may be selected.—HANTS.

PRESERVING FLOWERS.

SIR,—I have just read Mr. Bastin's note on "Wiring Flowers." When I lived in London and had to limit myself to a few shillings a week for flowers, and naturally wanted them to last as long as possible, I always used to tie a thread of ordinary sewing silk (cotton would do equally well) round the tulips. The petals were then held in position till the flowers were quite dead. This seems to me a simpler way than wiring.—MURIEL FEWSTER, *Dorset*.

PLANT IDIOSYNCRASIES.

SIR,—Not only, as is stated in THE GARDEN of January 30th, do some plants succed in one district and fail unaccountably in another, but one thing will thrive in my garden and die in my neighbour's. I had such a supply of culinary mint, which spread from a border and came up through the path, that I rooted it out entirely. Across the road my neighbour cannot get it to grow at all. I cannot grow the Madonna lily, having tried it often. Over a low dividing wall it grows and flowers on the same side of the road. Gentianella acaulis only produces small green flowers, the shape in miniature of what the true flowers are. Knowing that at my old home in the country there was a sapphire blue border of them, I sent my plants to a friend who lived close by in that locality. She told me she had had plants for years which never showed flowers at all. Carnations thrive with me, and I have often given rooted layers to a friend who lives at a distance of about five minutes' walk, and who has a much better garden than mine. The instant they are planted they fade and die. They make no attempt to grow. Even in the same garden the thing happens. I have the common purple-pink creeping phlox. It showed a sparse flower here and there. It lived and languished though in full sunshine. I transplanted it; it flourishes. It has been divided; its children flourish. I have now "purple patches" of it smothered in bloom.

One has to accept these mysteries, and, if possible, profit by accepting them. We shall all have gay and flourishing gardens if we remember what is called the "gardener's secret," *viz.*, only grow those flowers which will grow with you.—E. M. J., *Edinburgh*.

COLOUR AND NAMES.

SIR,—The recent articles and correspondence in THE GARDEN on the subject of colour description are most opportune. Would it not be possible for some authority like the R.H.S. to draw up a standard colour-chart to which both nurserymen and buyers could refer, to the great satisfaction of both? It would seem to be the only way to avoid the quite horrible confusion reigning at present, the commonest error now being to call the shades of purple, lilac and heliotrope "blue"! I know (to my cost!) that I have had more disappointments when purchasing (both overseas and locally) from *incorrect and misleading colour descriptions* than from any other cause, and doubtless countless others have suffered the same experience.

May I also voice a plea to the raisers of novelties for a little more ingenuity and originality in naming their productions? It has recently been my misfortune (I fear I must say) to see the catalogue of a very eminent raiser of a certain flower in the United States of America (who, for his own sake, should he read this, shall remain nameless) in which quite 99 per cent. of the flowers were named after people, and of these quite half the names were simply hideous and unsuitable for any flower. Please remember there are plenty of excellent and *reasonable* names still available, all that is required is a little tact and thought. But if you *must* name the plant after a friend, do use the name in as elegant a form as possible and not half a mile long or with fifteen initials tacked on—*for ornament!*—AUSTRAL, *Geelong, Victoria, Australia*.

DOMBEYA CAYEUXII.

SIR,—The white-flowered Dombeya lately in beauty at Kew so nearly resembles the pink-flowered Dombeya Cayeuxii that is grown in Riviera gardens that I hope for more particulars as to its name and where it originated. Dombeya Cayeuxii is a hybrid between an abutilon and the tender tropical dombeya, but is sufficiently hardy to flower in good seasons on the Riviera. Its large balls of clear rose pink tightly packed "mallow" flowers are most effective and decorative as they hang under the handsome foliage. If this white-flowered dombeya is a similar hybrid, it will be interesting to know where it can be obtained. It looks as if it were the same cross but with white flowers and less vigorous habit than D. Cayeuxii, whose robust growths demand both space and shelter. After the two incursions of frost this winter D. Cayeuxii has been much cut, so a similar but hardier shrub would be welcome. The Chinese abutilon (A. sinense) with its charming open bells of golden buff with a crimson eye is so hardy that a second crop with it would be very desirable.—E. H. WOODALL, *Nice*.

BLUE POPPIES.

SIR,—I do not understand Mr. Kingdon Ward (page 115) describing the plate of Meconopsis simplicifolia in the *Botanical Magazine*, t. 8364, as "exactly resembling" my figure of M. simplicifolia var. Baileyi in "Flowers—a Garden Note Book." In the former the flower is drawn of natural size, and the stamens are represented as set loosely round the ovary, with dark brown or black anthers; whereas my drawing of Bailey's variety as grown here shows the stamens densely crowded with anthers of clear golden yellow, contrasting admirably with the sheen of sky blue petals. Moreover, there is a stain of bright purple at the extreme base of each petal, which greatly enhances effect. I do not think the plate in the *Botanical Magazine* can have been taken from Bailey's variety; indeed, it is doubtful whether that form of the species was known in this country in 1913. We have not experienced the difficulty referred to by Mr. Kingdon Ward in growing this beautiful poppy, which takes quite kindly to a border soil of loam, peat and sand, and produces plenty of seed. Normally it behaves as a biennial, but in the summer of 1925 one of our plants flowered and ripened seed in the second successive season.—HERBERT MAXWELL, *Monreith*.

PRIMULA CAPITATA.

SIR,—In looking through some back numbers of THE GARDEN I came upon an article on Primula capitata written by the late Mr. Malby in 1912. In this he mentions that this primula is particularly desirable, as it has the "very great advantage of coming into blossom in autumn when nearly all the other primulas are over." This has not been my experience. It is true that the other primulas are over and Primula capitata is still "going strong," but it has outflowered the lot of them and has been blooming for over two months with no other assistance during the hot weather than a daily can of water. This makes it a summer bloomer here, though possibly old plants may behave differently. The colony that I have are last season's seedlings, and are growing in loam and leaf-mould in practically

What users are saying about The J·P SUPER

ALL UNSOLICITED.

From a Lawn Owner : "It is the easiest machine to work devised and renders a petrol-driven motor a superfluity."

From a Lawn Owner : "No effort is required to push the machine, which is a 16-inch."

From a Lawn Owner : "In addition to saving a man, our lawns are kept much nicer than ever before at much less cost."

From a Golf Club Secretary : "I would like to register my admiration of your Mower and gratitude for at last producing something so infinitely superior to the 'plumber's jobs' in mowing machines that we have had to suffer from so long."

From a Golf Club Secretary : "The Greenkeeper tells me it is easier, quicker and more thorough than any he has ever seen, and hopes he may never have to revert to the old type."

From a Gardener : "It is the most marvellous machine I have had anything to do with, and have used all the best makes in my time."

"It is so simple to adjust, easy running and best all-round cutting machine I know of. It is all you claim it to be."

full sun. Their flower-stems are well over a foot in height. Cockburniana flowered equally well in a similar position.—E. O. CALLAGHAN, *Hawera, N.Z.*

HYDRANGEA HORTENSIS ROSEA.

SIR,—I am indebted to Mr. Ivan Dunlop, Los Angeles, California, for his letter in your issue of February 6th, in which he suggests a firm from whom I might possibly obtain plants of Hydrangea hortensis rosea.

His letter, coming as it does from overseas, is an instance of the friendly interest which exists among readers of THE GARDEN. I have further proof of this, for my query brought me some very interesting correspondence and what is more, actual offers of plants from two sources. The first I gratefully accepted, and although the writer kindly offered me a small plant or two, when the plants came to hand one was a fine specimen, which should not fail to flower this year.

The donor also gave me particulars of his soil in which his hydrangeas are growing, but as I have not got his letter by me at the time of writing, cannot give authentic details. I do, however, remember that he shared the view of several who know H. hortensis rosea, *viz.*, that it is the most glorious blue among the family.

I shall, naturally, watch the behaviour of the plant growing in the natural soil of my own garden with keen interest.

I am grateful to THE GARDEN for providing me through its columns with the means of procuring plants, which may have been difficult to have obtained through the ordinary business channels.—ARTHUR J. COBB.

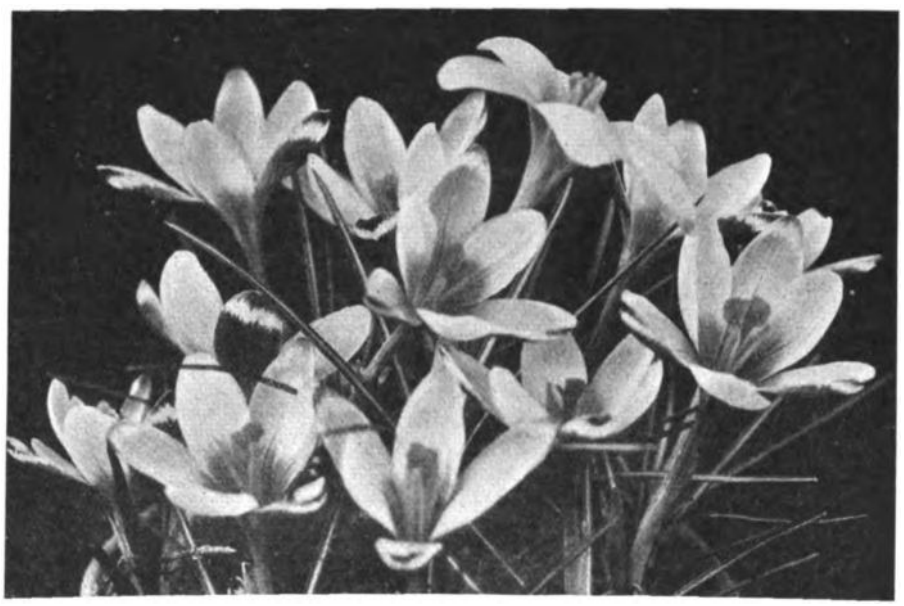
EARLY SPRING AT VINCENT SQUARE

THE recent mild weather conditions have not come alone. They have brought in their train a host of early flowers of all kinds from the greenhouse, the rock garden and the shrubbery. The display at the R.H.S. Hall, Vincent Square, on the occasion of the usual fortnightly show of the Society on February 23rd, was unusually bright and attractive for this period of the year. The contrasting tones of colour were quite a feature, which certainly augurs well for the future shows. Alpines predominated, while bulbous flowers, cyclamens, early-flowering shrubs and azaleas supplied the more brilliant patches of colour.

One of the most outstanding exhibits was that of cyclamens set up by Messrs. Sutton and Sons of Reading. As was the case last year, the plants were laid out in bold circular groups set in a bed of moss, and the whole arrangement was exceedingly effective. This style of exhibiting deserves every praise, as each individual variety can be appraised on its own particular merits and compared with its neighbours with great ease. The plants shown were excellent in every way—in size, vigour and colour. Among the varieties were to be found Giant White, a really excellent variety; Firefly, dainty and of good colour; Giant Salmon Pink; Vulcan, good both in foliage and flower; and Giant Shell Pink. There seems little doubt that, with the production of so many fine varieties during recent years, the cyclamen is the pre-eminent flower for indoor decoration during the winter months.

Near by, a rather interesting collection of new seedling potatoes was also staged by Messrs. Suttons. Rarely has such a collection been seen at the Hall. The varieties as yet are not in commerce, and they are all new and distinct seedlings, grown in the open field in Dumfriesshire, Scotland. In addition, they have passed the necessary tests for immunity to wart disease. All the tubers are of good shape and size, some smooth-skinned, others rough, while all show a tendency to shallow eyes. It was a most interesting as well as instructive collection, and indicates that our large seed houses are as much concerned with the raising of high-class vegetables as with the production of high-class garden flowers.

A large and outstanding group of forced bulbs of all kinds was exhibited by Messrs. R. H. Bath, and from such a fine exhibit one could fully appreciate the great value of tulips, narcissi, hyacinths and also crocuses when grown as pot plants for house decoration. Excellent varieties had been selected, and the bulbs were well grown. The crocuses were, perhaps, too tightly packed in the bowls; but the varieties Mikado and Queen of the Blues, nevertheless, looked most effective. Hyacinth L'Innocence, Narcissus Flame and the Tulip Vermilion Brilliant were especially fine. Bulb enthusiasts were particularly interested in the collection of seedling narcissi shown by the well known hybridists, Messrs. Barr and Sons. In many cases the varieties exhibited were not christened, but given under numbers. Of those already named, some of the finest were Village Beauty, Striking, John Evelyn, Eileen Terry and Lovenest, and all of these possess many good points which should give them great popularity when they become more generally known. An attractive display, crocuses growing in irregular drifts in a lawn, was made by Messrs. Carter and Co. The purple and mauve crocuses formed a pleasant contrast against the vivid green grass.



THE GAILY COLOURED CROCUS SIEBERI VERSICOLOR MAJOR.

An imposing group of apples which consisted of well over a hundred varieties was exhibited by Messrs. G. Bunyard and Co. A collection of forced shrubs was exhibited by Messrs. L. R. Russell. Fine specimens of the azaleas Van Thol and Anthony Koster, the fragrant Viburnum Carlesii, Prunus triloba and a group of handsome Amaryllis hybrids were shown. Mr. G. Prince staged a number of roses, among which were the yellow Banksian rose and that beautiful coppery red briar, Austrian Copper. Mr. Elisha Hicks again exhibited perfect blooms of forced roses. Rhododendrons and anemones were exhibited by Messrs. Gill and Son and a collection of shrubs of all kinds came from the nursery of Messrs. W. Cutbush and Son.

The colour, size and quality of the carnation exhibits left nothing to be desired. Messrs. Allwood Brothers' border carnations Sussex Flake and Sussex Rosalind, and their perpetuals Beauty of Durham and Edward Allwood, were clear in colour and perfect in shape. Messrs. C. Engelmann showed a new variety named Carola striata; and Messrs. Stuart Low had good blooms of Coquette, Lady Hindlip and Lord Lambourne.

The earlier alpines were in full force and flower. Most exhibitors showed some of the recent Kabschia hybrid saxifrages which have introduced a new play of colour into the alpine house, for which the choicer earlier-flowering saxifrages are really better suited than to the open air, where they are so liable to be tarnished and tattered by the rough weather.

Mr. C. G. Kirch, showed a very fine and well grown collection of alpines in pans, including Messrs. Prichard's hybrid saxifrage Delight, which is, perhaps, the purest pink of its class; the rare Saxifraga Tombeanensis, Hall's variety of S. oppositifolia, in which the striping of the type is emphasised and gives us a gay flower with broad lines of dark and light purple pink; and several of Sündermann's hybrids.

Mr. F. G. Wood of Ashtead made a very interesting and effective group of colour by massing the blue-black Muscari paradoxa against the clear purple of Sisyrinchium grandiflorum at the foot of a bush of Magnolia stellata covered with its dead white flowers.

Messrs. Clarence Elliott showed many vigorous plants of the rare Primula Allionii (and they received an award of merit for the pure white form), Sisyrinchium grandiflorum album, with its great bells of almost transparent white silk; Primula Winteri; and a large pan of Saxifraga Faldonside in silver and citron yellow.

Messrs. Waterer showed some very interesting "bulbous plants": Iris Purpurea var. Ruby, reddish purple; I. Sindjarensis, a

Digitized by Google

pale blue Juno; Anemone blanda var. Scythinica, milk white, stained outside with inky blue; I. stylosa var. angustifolia, a fine dark form; and Puschkinia libanotica, a beautiful and vigorous plant that should be more grown for the individual beauty of its white flowers lined with china blue.

Messrs. Rogers of Southampton showed their pigmy cypress, Cupressus tetragona obtusa minima, which grows not much larger than its printed name, and some fine plants of the vigorous and easy Soldanella montana.

Messrs. Prichard and Sons showed their newest hybrid saxifrage, His Majesty, a handsome, striking flower with very large, overlapping white petals and a conspicuous ring of orange at the insertion of the stamens; and Riverslea, with very bright, rosy magenta flowers that contrast admirably with the silver foliage: it is vigorous and free-flowering and probably the best of its colour.

Messrs. Cutbush made a bold group of Kurumi azaleas round a bush of the pink peach Clara Meyer which rather overshadowed the queer, quiet colouring—transparent greenish white—of the rare Juno, Iris palestina.

Messrs. Reuthe showed the gentian blue, white-throated Tecophilea cyanocroceus; a very charming old double red primrose with a white line round the edge of the petals; and several double hepaticas, including the rare double white.

Messrs. Tucker of Oxford showed Morisia hypogæa, that odd little alpine which carries small stemless buttercups, smelling of hawthorn, on a rosette of dandelion leaves, but turns out to be a crucifer; Soldanella alpina; the pale S. Sanderii; and well flowered plants of Saxifraga Irvingii.

Messrs. Charlesworth and Co., Hayward's Heath, arranged a fine exhibit of choice hybrids, noteworthy examples being Odontoglossum Zulu, with a branched spike of fifty-eight flowers; Miltonia William Pitt, in which the labellum is effectively suffused with crimson; and Odontoglossum Serapis, whose flowers are heavily blotched with chocolate red. A silver-gilt Banksian medal was awarded to this group. Messrs. Sanders, St. Albans, were similarly rewarded for their exhibit of fine cymbidium hybrids, various oncidiums, and several excellent examples of Phalænopsis Schilleriana.

Silver Banksian medals were won by Messrs. Cowan and Co., whose group contained a fine variety of Cattleya Enid alba, as well as C. Tityus and C. Octave Doin; while Odontioda Princess Mary came in for appreciation on account of the bright nature of its large reddish flowers. Messrs. Stuart Low and Co. included the elegant Angræcum eburneum in their group, also several well flowered dendrobiums, the brightly coloured Lælia harpophylla, and Lælio-Cattleya General Maude, with a roundly formed flower of bright purplish rose. Messrs. Black and Flory staged a number of cypripediums, of which one bearing the name Robert Paterson was above the usual size, while the colour was also good. Mr. Harry Dixon had an exhibit in the centre of which stood a vigorous example of Dendrobium Melpomene, with numerous flowers of light yellow.

Messrs. J. and A. McBean exhibited various hybrids, including Cattleya intertexta alba, with pure white flowers; C. Cowaniæ alba, also pure white; and Odontoglossum Dictune, noteworthy for its flowers of immense size with the segments boldly blotched with red-brown. Mr. E. R. Ashton, Tunbridge Wells, staged the Broadlands' variety of Odontoglossum St. George, with a spike of nineteen flowers. Mr. G. W. Bird, West Wickham, exhibited Odontioda Gladys, with pleasing flowers of rose-violet blotched with red. Mr. G. F. Moore, Bourton-on-the-Water, showed Cypripedium Mrs. Eley and other notable hybrids from his well known collection.

NEW AND RARE PLANTS.

AWARDS OF MERIT.

CYRTANTHUS O'BRIENII.—The large, graceful flowers of this species are of a delicate coral red in colour and are borne in umbels comprising six to eight flowers, on scapes reaching almost a foot in height. The upper segments of the perianth are slightly overhanging, which has given to this species its other name of C. inæqualis.

VIBURNUM FRAGRANS CANDIDISSIMA.—This is a form with pure white flowers borne in dense clusters at the same time as the leaves are appearing. The flowers are all of the same size as in the type and only differ in colour; they also appear considerably later. The fragrance was much in evidence, due to the plant being indoors. These plants were both shown by Sir William Lawrence.

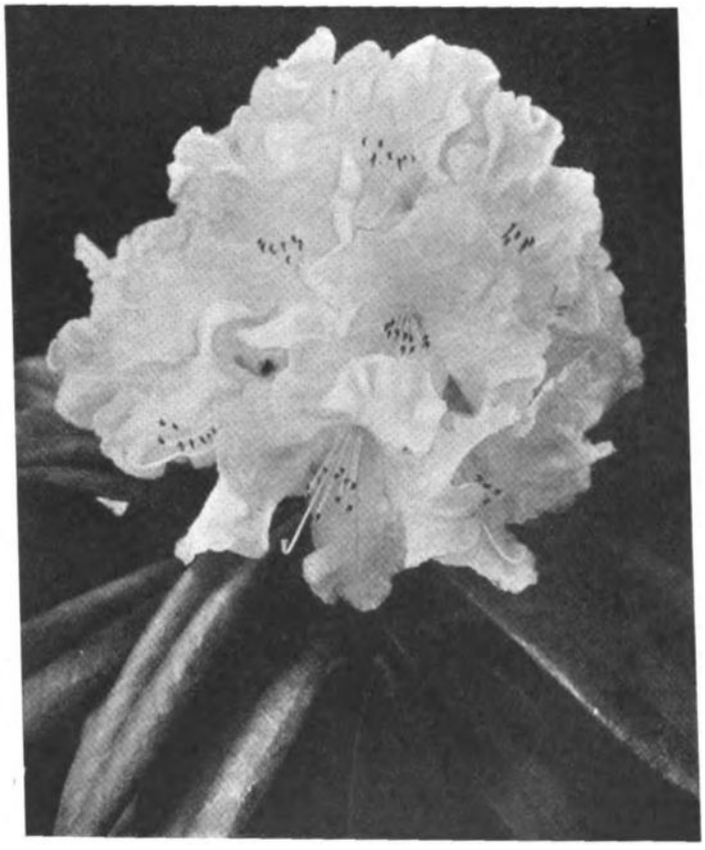
SAXIFRAGA RIVERSLEA.—This is a new hybrid between S. Goldroneana and S. lilacina with deep purplish rose flowers borne on slender stems 2ins. to 3ins. high. The foliage is also rather attractive, with a silvery appearance. Shown by Messrs. Prichard and Sons, Christchurch, Hants.

PRIMULA ALLIONII ALBA.—A pure white form of what Farrer called "the jewel of jewels among our European saxatile species." This is a most delightful form, with tight cushions of grey-green foliage as in the type, with the thin, shapely white blossoms peeping from it on very short stems. A rare treasure, which was well grown. Shown by Messrs. Clarence Elliott, Stevenage.

RHODODENDRON NOBLEANUM ALBUM GILL'S VARIETY.—As shown, this is an exceedingly fine variety, carrying fair-sized and closely set trusses of pure white flowers of some 2ins. across and spotted with delicate green on the throat. The foliage is of a light green. Neither the individual flowers nor the truss bears much resemblance to Nobleanum. Rather would it appear to be a hybrid form, with probably caucasicum blood in its constitution. Shown by Messrs. Gill and Son, Falmouth.

NARCISSUS POETAZ CHEERFULNESS.—The creamy white flowers of this variety are gracefully borne on tall slender stems. The outer petals are well spread, crowned in the centre by a tight bunch showing touches of yellow at the base. Shown by Mr. J. W. Barr, Wimborne.

CROCUS SIEBERI VERSICOLOR MAJOR.—This is a very fine, vigorous-growing form and larger in stature than the type. The flowers show the same intensity of colour in the throat with deep orange which fades to a delicate white, while the deep purple on the reverse of the petals is most striking and provides a vivid contrast. First-class certificate. Shown by Mr. E. A. Bowles.



THE HANDSOME TRUSS OF RHODODENDRON NOBLEANUM ALBUM GILL'S VARIETY.

ORCHIDS.

MILTONIA LYCÆNA, STAMPERLAND VAR.—One of the finest of the Miltonia hybrids. The spike bore three large flowers in which the petals are almost covered with a rich crimson colour; the labellum has the greater part of its area similarly coloured, while the base bears a brownish mask, with radiating lines, and surrounded with a lighter zone. A conspicuous feature is the yellowish crest. Shown by Mr. Robert Paterson, Glasgow. First-class certificate.

BRASSO-LÆLIO-CATTLEYA NIGERIA.—For a hybrid of Brassavola Digbyana this is unusually well coloured, the large flower has the sepals and petals of a deep rose colour, the labellum of a darker tint, with purple venation, and the throat with an orange-yellow disc. Award of merit.

VUYLSTEKEARA MELBA.—An interesting hybrid obtained by crossing Vuylstekeara Brewii with Odontoglossum Gorizia. The whole flower is of a rich crimson-purple, the broadly developed labellum showing more purple than the other segments. In formation it exhibits much of the character of Miltonia vexillaria. Award of merit.

ODONTOGLOSSUM CITRINUM VAR. PRINCE OF ORANGE.—A distinct hybrid composed of the three species crispum, Pescatorei and triumphans, and of which yellow-spotted varieties were used. The spike bore ten flowers of saffron yellow colour, with spotting of deep yellow. The labellum bears the characteristic blotch of O. triumphans, but of light yellow colour. The above three were shown by Messrs. Charlesworth. Award of merit.

CYMBIDIUM FLAMINGO VAR. ROTUNDIFLORUM.—A charming hybrid, produced by crossing Alexanderi with Merlin. The plant carried two spikes, with three and four flowers respectively, the segments broadly formed, blush tinted, the labellum with a crimson blotch on the front lobe, and rose staining on the lateral lobes. Shown by Lieutenant-Colonel Sir George Holford. Award of merit.

GREENHOUSE FUMIGATION

VIVID recollection of the shudder with which, in apprenticeship days, I heard the chief's order that the long range should be fumigated in the evening compels me to maintain that fumigating in the old style with tobacco paper dropped on to glowing cinders was the one really repulsive task in the routine of garden work.

Happily for all concerned, the scientist grappled with the problem, and although we still find in nicotine one of the most serviceable and reliable of insecticides for indoor use, we have it placed at our disposal in such a form of purity and certified strength that there is a remarkable degree of certainty about the whole procedure of fumigating with nicotine, and, greatest advantage of all, there is no necessity whatever to remain in the house during the process of fumigation.

It is important in the first place that this remarkable difference between the fumigating methods and materials of past and present shall be quite clearly realised, for the simple reason that some horticulturists of long experience are wont to condemn fumigation, bearing in mind only that which they long since proved to be wholly unsatisfactory, and for the further reason that the younger generation of plantsmen may realise that since fumigation has been reduced to a scientific operation the only means of ensuring success is to carry out the task with precision and exacting care in every detail.

Equally important is the necessity for a very clear understanding of the purposes, the capabilities and the limitations of greenhouse fumigation. The purpose in view will be readily agreed to be the destruction of plant pests, but it must be candidly admitted that while nicotine is extremely powerful and effective against many enemies of plant life, it is not capable of killing all foes or curing all diseases of plants. I have known actual instances of nicotine fumigation being used in the hope of checking mildew on pot roses and shanking in grapes, while I have heard a shop salesman assert that it will kill earthworms in plant pots.

The greatest value of nicotine as a fumigant lies in its power to kill aphides and some other small insects which infest various kinds of greenhouse plants, and because the fumes or vapour will penetrate chinks and crevices in staging, shelves and every corner of the greenhouse. Pests which take shelter against sprays or powders may thus be pursued to their lairs. It is well within range of possibility to kill red spider, thrip, mealy bug and snowy fly with nicotine fumes, but, on the other hand, if either of these four wretched pests gains a strong foothold in a greenhouse there will invariably be sufficient left uninjured after fumigation to restock the house and perpetuate the mischief; they require special measures, such as cyaniding, sulphurising or spraying with preparations which kill by contact. There is material here for further articles, but for the time being nicotine fumigation is all-sufficient to occupy our attention.

The commodity is put up in various forms by different firms. Some sell an almost pure nicotine with just sufficient of a volatising agent to ensure rapid and complete vaporisation. The well known firm of G. H. Richards, whose XL All brand of liquid nicotine fumigant has had many years of widespread use, still maintain a strong position in this trade, and it speaks well for the utility of this form of nicotine that while XL All is still as widely used as ever there are quite a number of other brands on the market the basic principles of which are practically the same, thus testifying to the fact that the use of such fumigants is carried on to a vastly increased extent.

The two principal points about this form of nicotine fumigant are: One, that the exact quantity required to ensure maximum results combined with safety of the plants is easily ascertained by measuring and working out the cubic capacity of the house; two, that when the lamps are prepared and lighted the house may be left with assurance that the task will automatically complete itself.

The compound is obtainable in the form of solid cakes or tablets instead of in liquid, but the only possible advantage I can attribute to the cakes is that they may be carelessly dropped without suffering damage, whereas a bottle may be broken, with the resultant loss of its expensive contents. Plants should never be syringed before fumigation, nor should the atmosphere in the house be heavily charged with moisture.

Evening is the best time for fumigation, but if it must be done by daylight choose a sunless day.

Obviously all openings should be covered, gaps under doors matted over, and everything be done to prevent escape of the fumes, and the house should remain closed until the following day, when it will be advisable to ventilate freely, for nobody should loiter in a house surcharged with nicotine fumes, which are rank poison. Most plants, except those carrying fragile flowers and such ferns as maidenhair, Asparagus plumosus or gymnogrammas, will appreciate a copious syringing with tepid water the day following fumigation. In regard to the exceptions named, there should seldom be necessity to fumigate the ferns if their culture is sound, and in the case of fragile flowers all necessary fumigation should be done before the plants begin to bloom.

There is no particular season for fumigating, but the prudent plantsman will make a point of fumigating once or twice quite early in the year, before he has tender young seedlings to consider, and probably during April another couple of fumigations may be required, and unless fresh plants are brought into the house with an accompaniment of unwelcome pests, the probability is everything will remain clean well into the summer months.

A single fumigation may suffice to kill ordinary green fly, but more stubborn foes, such as thrip, will only succumb to repeated fumigations on two or three consecutive or alternate nights.

Other preparations of nicotine than those above mentioned are obtainable, some in the way of sheets, which are to be ignited and left to burn out as in the well known McDougall sheets; others are cones either themselves to be lighted or evaporated by means of small candles. Where all are efficient it would be of little service to attempt to indicate a preference for one or another; the only point that sometimes needs a little careful consideration is that, as these ready-made quantities are usually measured to meet the needs of a certain cubic area, it will be perhaps a matter of difficult calculation to use the precise quantity required for a particular house. Needless to say, poisonous fumigants cannot be used in conservatories which have direct communication with the rooms of a dwelling.

THE GARDEN AND ITS NEEDS

THE GREENHOUSE

ABUTILONS.

ABUTILONS are classed as greenhouse evergreen shrubs. The foliage is handsome and graceful, and this character of the plant is considerably enhanced when the flowers are open. In a warm greenhouse it is possible to have flowers on the plants nearly the whole year; a little judicious stopping of some of the young shoots from time to time causes more shoots to grow, and directly flower-buds form a little feeding will strengthen both plant and flower. They are useful as pot plants and also for training to pillars and back walls in lean-to greenhouses and conservatories. Plants raised from seeds flower in the autumn of the same year if grown in a warm greenhouse. The seeds should be sown in March in pots filled with a mixture of fibrous loam and leaf-soil in equal proportions. The resultant seedlings should be potted singly at an early stage of growth and re-potted twice, the last time in 6in. pots. Use a similar compost throughout, but in a coarser or more lumpy condition. Retain the young plants in the greenhouse throughout. Cuttings of young shoots about 4ins. long will root readily in a propagating frame in the spring. The soil for the cuttings should be fine and surfaced with coarse sand. Sever the cuttings just below a joint, or have a tiny heel of older wood attached to it. These young plants will form good specimens 18ins. high by September. Old plants may be planted in sheltered beds in the flower garden, where they will bloom freely during the summer months. If they are retained in their pots and the latter plunged, there is not much trouble entailed in rehousing in October. The colours are lovely, pure white, yellow, orange, orange-red, white

SALE OF ROSES

At 33⅓ per cent. less than catalogue prices.

HAVING so far sold our stock of Roses that the catalogue is no longer a reliable source of selection and not having enough each of different kinds to justify advertising the balance in named collections, we are offering what remains of our stock of bush, standard and climbing Roses in carriage paid quantities in varieties of our selection, at 33⅓ % less than list prices.

The varieties are all first-class (not an obsolete one among them), the trees are excellent and, while all buyers will get remarkably good value for money, the first comers will have the advantage of newer and more expensive varieties for as long as stocks last.

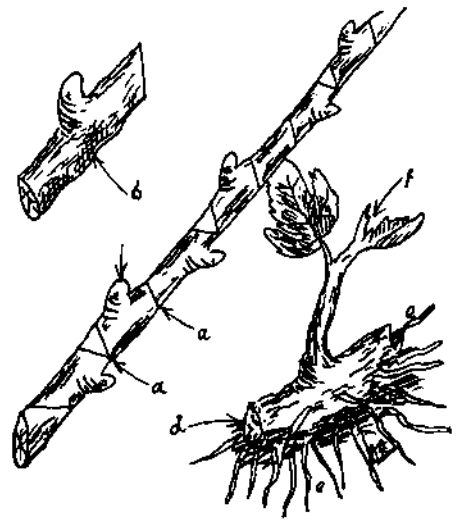
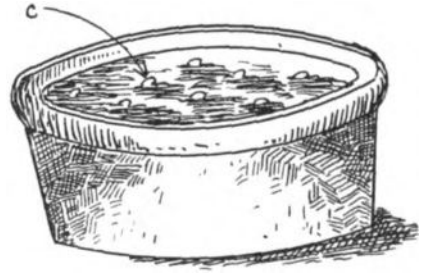
and carmine, pink, orange striped red the foliage of some are green mottled with yellow.—G. G.

GROWING GRAPE VINES FROM EYES.

THIS is very interesting work indeed. Many amateur cultivators like to grow their own young vines, and they are frequently successful. Prunings that have been kept in a cold place are suitable now for cutting up. The extreme ends of the side shoots pruned off should be discarded. Those eyes that do not possess an embryo bunch of grapes in each one are the best for our purpose, but as nearly all buds do contain an embryo bunch, the latter should be carefully cut out when just sufficiently developed as to be distinct from the shoot. The beginning of





March is a suitable time for amateurs to insert the buds, because the latter should begin to grow soon after and continue to do so without any check. If they are left in a cold, wet soil for a long time, the wood is liable to decay—the bark portion from which the roots grow. Provide a few pans or pots, three parts fill them with a very sandy loam and a small quantity of leaf-soil. Place coarse, washed sand thickly on the surface. Be sure that the drainage is good. Cut the eyes as shown at *a*, *a*, about ¼in. above and the same distance below the bud, denoted by the arrow. When severed, you may cut away a small slice of wood and bark, shown at *b*. Insert the buds as at *c*. When the new roots are about 1in. long, shown at *d*, *e*, *e*, carefully lift from the pan and pot each growing bud, *f*, separately in small pots. For about ten days it is beneficial to plunge the small pots in the warm bed, too.

THE FLOWER GARDEN

HOW TO GROW FUCHSIAS FROM CUTTINGS.

FUCHSIAS are all round useful plants quite independent of the charm of the flowers which are produced on well grown plants throughout the summer months. They are

valuable subjects for the greenhouse and conservatory, dwelling-room window and flower garden. Groups of the plants in pots, the latter being sunk just below the grass on the lawn, look charming, especially in recesses, partly shaded and backed by evergreen shrubs and trees. There will be numerous shoots available for cuttings in March. These shoots should be inserted in a light, sandy mixture placed in small pots. The latter should be sunk to their rims in ashes or leaf-soil in a frame or box, temporarily placed on the stage in a greenhouse. Judiciously watered and shaded the cuttings root quickly. Then they must be potted singly, also in a light compost and again re-potted before the pots get too full of roots; as, if they do, the free growth of the stems and leaves will be checked. It is while the plants are young that the form they are to take must be decided upon. If standard then allow the shoot to grow and be trained to a neat stick until it is the desired height—2ft. 6ins. or 3ft.—before the point is pinched out to induce head shoots to branch out. If bush, pinch off the end of the leading shoot when the latter is 9ins. high. A bush or a pyramidal specimen can be grown from the same stopping. For all main repottings mix with the compost pounded bricks, mortar rubble and bone-meal. These pot plants may be grown on a bed of ashes outside during the summer.—G.

VIOLAS.

VIOLAS, also called tufted pansies, will thrive in any ordinary garden soil and in wet ground, where many kinds of summer-flowering subjects would fail. Violas are extremely useful in the flower garden as the plants are suitable for wholly filling a border, for a groundwork to taller-growing subjects and as neat, compact flowering edgings to borders. Old plants that have become straggly should be lifted, divided and replanted. Indeed, if the present is the second year of the growth of a viola plant, it should be lifted, carefully divided and the small rooted parts planted in a prepared border at a distance of 6ins. apart. If the soil is light do not add any other kind to it, if of a very heavy nature, then mix some sifted leaf-soil with it; the leaf-soil will induce new roots to grow quickly and thus fit the small tufts for planting out directly the beds are cleared of bulbs and other spring-flowering subjects. Directly these divided plants begin to root freely, flower buds will form and all should be pinched off until about ten days or a fortnight after planting-out work is finished. Throughout the season the faded flowers and their stems should be regularly removed from the plants then the latter will continue to bloom until the beds are required for spring-flowering plants again. Where naturally clayey soils obtain, place a small handful of burnt soil from the garden smother-fire round each viola at planting time to encourage early growth of new roots.—HANTS.

GLOBE THISTLES AND SEA HOLLIES.

JUST as one sometimes finds stocks and asters grown in the same border, so also it may often be seen that globe thistles (echinops) and sea hollies (eryngiums) are closely associated in a garden. March and April are convenient months during which to plant the clumps, and if some old manure is incorporated with the soil the majority of the plants will bloom the same season. The old idea that late autumn planting was the best is not so largely adhered to now, and, provided they are looked after with the water-pot should the succeeding season following removal be dry, there is no reason why the display should not be good. Both the plants, as it is known, are extremely hardy, and the past winter, severe as it has been, has not affected them adversely. To have the best from echinops and eryngiums, they should

be given a position where they will get every gleam of sun. Echinops Ritro and E. sphærocephalus are among the best of the blue forms.

Eryngium Oliverianum, steely blue stems and bracts; E. amethystinum, purplish stems and amethyst-purple bracts; E. planum, with numerous thistle-like heads, bluish in colour: are familiar sorts that have a wide popularity. If intended for winter decoration, the stems should be cut before the bracts open and carefully dried.

Both the families can be raised from seed sown in a cold frame in April, and the plants will commence to bloom the following year. —CLAREMONT.

MISCELLANEOUS

RENOVATING LAWNS.

THE grass on lawns, tennis courts, bowling greens and cricket grounds must receive regular attention all the year round if it is to remain closely grown, green and healthy—that is, needing to be cut regularly in normal summers. Something can be done during the summer months to feed the growing grass, but not as much as can be during winter and springtime. The recent rains have shown up the wet parts of many lawns; it is not always desirable that such should be specially drained, as in normal seasons they do not require such drastic treatment. Patches of the kind named should be eased up by inserting the prongs of a strong garden fork at distances of 9ins. apart and each time prise the turf upwards. Surface lifting is not sufficient; the fork should be inserted each time approximately 7ins. deep. After the work is done, do not tread upon the turf nor roll it until drier weather has been experienced for some time. All moss found should be raked off and a liberal dressing of rich soil and a small quantity of lime applied. The soil, sufficient just to cover the grass before it is brushed in, and the lime at the rate of 4 oz. per square yard. Early in April, apply bone-meal at the rate of 2 oz. per square yard. There are often open joints, in the case of newly laid turves, to be dealt with when the first fine weather comes. Do not fill up such with ordinary soil if marl or clay can be procured. The latter should be dried, pounded to a powder, the open spaces filled with it; then a wonderfully good, firm lawn ground will result.—HANTS.

CATALOGUES RECEIVED.

Messrs. Maurice Prichard and Sons, Riverslea Nurseries, Christchurch, Hants.—List of alpine and herbaceous plants.

Messrs. Stuart Low and Co., Bush Hill Park, Middlesex.—Select carnations for 1926.

Mr. Alfred Edwards, Fordham, Ely.—A select list of gladioli, together with numerous cultural hints.

Mr. T. Smith, Daisy Hill Nursery, Newry.—List of seeds of hardy plants.

Messrs. Storrie and Storrie, Glencarse, Perthshire.—List of seeds and seedlings for 1926. A wide selection is offered.

Messrs. McHattie and Co., Seed Merchants, Chester.—Selected list of farm seeds.

Messrs. Hunters, Chester.—Forty-fourth annual list of agricultural seeds.

Messrs. The Darlington Fencing Co., Limited, Lloyds Avenue, London, E.C.3.—Two interesting and instructive little brochures on wire fences. In one, "'Ware Wire," all particulars of galvanised wire are set forth in an interesting style, with numerous illustrations. The other is a price list and indicates the many uses to which galvanised wire may be put. All kinds of wire fences and also wire gates, tree guards, chestnut paling fence, oak fencing, etc., can be supplied. A wide selection is offered and it is a price list which all keen horticulturists and agriculturists should obtain.

MORE PROFIT THROUGH EXTRA YIELD AND *IMPROVED QUALITY.*

MATTHEWS' LAWN SAND

Effectively kills all the common weeds in lawns, and at the same time acts as an excellent Fertiliser. Sprinkle evenly over the weedy patches, at the rate of 3-ozs. per square yard, in dry weather Repeat at intervals of a few weeks, till the weeds are killed. The grass will become brown and appear to be burnt, but it will recover, and the useful grasses will grow more vigorously.

WAKELEY'S *Celebrated* Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

AS USED IN THE GARDENS OF GREAT BRITAIN

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

Please mention THE GARDEN *when writing.*

ALPINE PLANTS, BORDER PLANTS, CHOICE FLOWERING SHRUBS, MINIATURE CONIFERS, HARDY HEATHS, HARDY FERNS, CLIMBERS. One of the oldest, and perhaps the finest, all-round collection in the country.

We grow some 4,000 kinds of all the best outdoor garden subjects, including such items as 100 kinds of Michaelmas Daisies, 100 kinds of Campanulas, 50 kinds of Hellebores, 200 kinds of Saxifrages, etc.

Our Catalogue of these is beautifully illustrated, shows how to build a rock wall and water lily pool, and tells about soils, etc., etc. It makes a fine reference book on plants. It is sent post free for 1s. which may be deducted from orders.

Seedlings Thrive and Don't Die

off after being transplanted owing to root disturbance or breakage, if brought up in Patent

MILLIONS SOLD ## T. P. SEED RAISERS **NO SLUGS**

because no disturbance can take place.

FOR ANNUALS, as Godetias, Clarkias, Larkspur, etc., *USE* BABY T.P. SEED RAISERS (measuring 1¼in. across by 2in. deep). Sow 2 or 3 seeds per Raiser, pull out to strongest. It will develop strong root growth till planting-out time comes, when Raiser (by that time rotted) will peel off, allowing seedling to be put in soil without knowing it has been touched.

FOR SWEET PEAS *USE* T.P. PEA RAISERS (size 1¾in. across by 4½in. deep). Sow 1 seed per Raiser. You will be delighted with good root action and quick development after planting out.

You get stronger plants, guaranteed to grow well with less labour.

T.P. Raisers take up much less room and retain moisture thus requiring less watering, are easy to handle in bulk and do not break, and ensure good plants, thus saving seed wastage.

PRICES in U.K., cash with order, carriage paid—
Baby" T.P. Seed Raisers, one strong seedling tray with 54 **"Baby"** Raisers complete. 1 for 2/6; 2 for 4/9; 3 for 6/9; 6 for 13/-; 12 for 24/6. **Refills ("Baby"** size), 108 for 2/7; 216 for 4/10; 324 for 7/3; 540 for 11/3.
T.P. Pea Raisers, one wooden box having hinged side with 48 Raisers complete. 1 for 4/3; 2 for 8/-; 3 for 11/6; 6 for 22/6.
Refills. Pea size, 100 for 3/-; 200 for 5/9; 300 for 8/3; 500 for 13/6
Order NOW from your Seedsman. If he does not stock, send direct to Sole Makers:

SPRING PLANTING.

We get many letters from customers asking if it is too late to plant Fruit Trees and Roses. So far from this being the case, nurserymen do most of their own planting at this time of year. Fruit trees planted now will be much more likely to fruit than if put in in the autumn.

All orders are despatched the day after receipt.

George Bunyard & Co., Ltd., The Royal Nurseries, Established 1796. Maidstone.

NEW HARDY CRIMSON BROOM

AT Chelsea Show (1925) the King said, "That red Broom is certainly very striking." This was the new crimson Broom "Dorothy Walpole," which received the unanimous Award of Merit from the R.H.S. as well as other distinctions in London and on the Continent.

In the *Field*, a well known ex-Curator of Kew Gardens wrote: "The richest coloured Broom known is one named 'Dorothy Walpole.' It is as hardy as the common Broom . . . and is very free-flowering . . . the colour is rich velvety crimson . . . more attractive than any of the coloured Brooms yet seen." The colour far surpasses Cytisus Dallimorei, and the growth is as vigorous as C. Andreanus; it requires no special treatment nor any kind of protection whatever—just a hardy shrub for ordinary garden soil in any part of the British Isles, however far north.

A Vice-Chairman, Floral Committee, R.H.S., wrote: "Everyone who has seen my plant has been astonished at its warm glowing red," and from a lady in Devon: "I am so delighted with the Broom 'Dorothy Walpole.' It has done splendidly and is like a sparkling gem in the garden—one mass of flower."

Strong pot-grown plants now ready for planting out, to flower in May, 12/6 each. Carriage paid rates to any station in Great Britain or Ireland: One plant, carriage paid, 15/-; two plants, carriage paid, 28/6; three plants, carriage paid, 41/-; six plants, carriage paid, 79/6.

THE PRUNING OF SHRUBS

SOME weeks ago I mentioned that I had cut out quantities of wood from several shrubs, such as philadelphus and Spiræa sorbifolia, to see if this would make them flower. Since then I have been making enquiries of my friends about the whole question of pruning, and have come to the conclusion that general pruning is a little understood art and one that is even less practised. In THE GARDEN of February 6th were two letters in answer to a correspondent's complaint that he had failed to flower Lonicera fragrantissima. The writer of one of these letters said that he pruned it hard; the other that he left his plant alone. Both were obviously successful in flowering this plant, and yet they used diametrically opposite methods. A friend of mine told me that he had admired a by no means large plant of Viburnum fragrans in full bloom in Mr. F. G. Wood's nursery. Now, one of the usual complaints about V. fragrans is that it is by no means a free flowerer. Mr. Wood attributes his success to the fact that he topped it. These are but two samples of information that can be picked up.

I am sure that in most gardens—and even large gardens—there is not nearly sufficient attention paid to pruning. It is true that a few plants, such as roses and Buddleias variabilis and Veitchii, are cut back every year as a matter of course: it is equally true that most other trees and shrubs are left severely alone. One argument sometimes heard against pruning is that plants are never pruned in the wild state, therefore the use of a knife is surely unnecessary when the finders write so eulogistically about the magnificent specimens they have found in the wilds. The answer is that no collector has ever seen such fine specimens, with very few exceptions, in the wild as a well grown garden plant. This, of course, only applies to plants that like our climate and conditions.

I should point out that by pruning I do not mean cutting back either to the ground or to the main stem. It is difficult to pin even a specialist down to what he considers the correct method of pruning individual shrubs, particularly newer introductions. It is fairly obvious that not only each genus but each species requires different treatment, but I am certain that a better quality of plant would result if the knife was used with moderation. Something should be learnt of the habit and growth of the shrub before anything is attempted. In the past, in my own garden, I have been accustomed to leaving my shrubs alone, and it is only in the last two years that I have started to use the knife. I use no rules, for I know of none—other than that those plants which flower before the leaves, flower on the old wood; and that the majority of those that flower after the leaves, produce their blossom on the present year's shoots. On the other hand, common sense teaches one a good deal: that too much growth prevents the ripening of the wood, so the shoots should be thinned to let in light and air; that all damaged, diseased and dead wood should be rigorously removed; that if a plant is growing in too spindly a fashion, it should be topped to promote side growth; and so on.

A good example of the value of pruning is in Potentilla fruticosa and its relatives, which I consider to be short-lived plants. If the old wood is heavily cut out, it promotes new growth and the plant responds. If the old wood is not removed, it languishes and no new growth is formed, with its subsequent death. I have lost several of these plants through neglecting to use the knife.

I am sure, also, that a little, if done every year, is better than a sudden inroad on a shrubbery and a persistent hacking off of branches. For one thing, most people like chopping—and pruning fever, a very easily caught complaint, will make you overdo the hacking and lopping and chopping. Many old shrubberies which exist in hundreds of gardens would have been better for a little judicious pruning years ago. The plants would now be shapely specimens instead of overgrown, lanky, gawky objects that are a credit to no one.

I am sure that many readers of THE GARDEN would be interested to hear of the experiences of others in the pruning of shrubs, not those planted as solitary specimens or for exhibition purposes, but the ordinary denizens of the shrub border or wild garden. First-hand information I find difficult to get, but I am sure that much can be done to make an all-round improvement, not only in the shape of the shrub but also in its flowering qualities. Of course one proviso should be made, and that is that the pruning knife should not be used so hard that it destroys the grace and shape of a plant; but it should not be a difficult task to strike a happy medium.

SHRUBS FOR WALLS

BY W. J. BEAN.

AMONG the many phases comprised in the art of gardening, that of the cultivation of plants against walls is one of peculiar interest. The growing of fruit trees is not in consideration in the present article, which is concerned with purely ornamental things, yet the fact that in many parts of the country success with certain fruit-bearing trees, such as figs, peaches and apricots, can only be achieved with the aid of walls, points to a corresponding value in the culture of decorative plants also. Walls, indeed, are as great an asset to the cultivator of ornamental shrubs as they are to the grower of choice fruits. Lucky is he whose garden includes some walls 10ft. or 12ft. high, especially if they are of brick and their

THE GOLDEN BLOSSOMS OF FREMONTIA CALIFORNICA.

colour mellowed with years. Stone walls are not to be despised, but the wide spacing of the mortar layers often makes the attachment of the branches to the wall inconvenient without some form of wiring, which adds to the expense and is not good for the plants.

The two factors which help plants growing against walls are, of course, the shelter they obtain and the greater heat they are able to enjoy there—heat that is not only intensified during actual sunshine, but which is conserved by the wall and radiated during the night. There may, in consequence, be grown there a numerous class of plants which are scarcely hardy enough to succeed fully in the open yet do not absolutely need greenhouse treatment. In this category will be found plants from the south of Europe, north Africa, the Himalaya, the warmer parts of Japan, Australia, New Zealand, the warm temperate parts of South America and California. There are, besides, a number of shrubs which, although perfectly hardy, flower much more freely when planted against a wall.

On the whole, a wall facing south-west is probably the best. It receives a great proportion of all possible sunshine, yet the plants against it are protected from the early sun that so frequently follows a frosty night in spring and often works mischief by too quickly thawing young shoots and flower-buds. But with the exception of those facing due north, which present special problems, all walls are valuable, even those facing east or north-east. For these, shrubs should be selected that commence to grow late and flower after April, giving, if possible, those that flower earlier a southern or, preferably, a western frontage.

The differences in the cultivation of wall shrubs, as distinct from those ordinarily placed, are chiefly in training and pruning. A shrub merely planted close to the base of a wall and left to grow in its natural way enjoys advantages that will often enable it to succeed in districts where it would otherwise fail. Very good examples of such shrubs—more or less tender—may be seen planted between the buttresses of the outer walls of the Temperate House at Kew. A succession of mild winters has no doubt flattered one's hopes unduly, and a real stinging winter, putting us back to the scratch mark again, will leave some woeful gaps. Still, in gardening, there is much to be said in favour of Herrick's injunction to enjoy the rosebuds while we may. Here, at any rate, without being attached by nails or otherwise to the walls, the pomegranate has borne fruit abundantly, Fremontia california flowers freely, and even Erica melanthera has blossomed beautifully for some years past. Tender shrubs of slow growth and of a habit too stiff to be trained easily against a wall may well be tried in such places. But in the present article I am more concerned with shrubs which, planted at the base of a wall, can be trained so as eventually to clothe it from top to bottom. To effect this, their growths have, of course, to be trained upwards and sideways, and a regular system of pruning has to be carried out.

Where the walls are built of bricks I think the old-fashioned system of training the shoots with nails and shreds of cloth has not been improved upon. But where the walls are stuccoed or built of large stones a system of strained wires to which the shoots can be tied becomes necessary. The closer this wiring is to the wall the better. This plan affords a very convenient means of training, but in course of time the wires perish and break, and there is the defect that during very cold weather shoots actually in contact with the cold metal may be injured or killed. By a little management this defect may to some extent be obviated by placing some non-conducting material, like a shred of cloth, between the shoot and the wire, or even the tying material may be so arranged as to serve the same purpose to some extent.

As the shrub grows older and the stems and branches thicken they usually become self-supporting, and nailing and tying become necessary at the extremities only.

PRUNING.

The method and time of pruning is largely dependent on the time of year the shrub flowers and on its mode of growth. Those that flower early in spring, say during March and April, on growths made during the previous summer, such as Prunus triloba flore pleno, should be pruned by simply cutting back the shoots that have flowered nearly to their base as soon as ever the blossoms have faded, thus leaving practically an entire growing season for the shrub to make new shoots for flowering the following spring. The same method of pruning must be adopted for those that flower later in the year on shoots of the current season, such, for instance, as Vitex Agnus-castus or the tecomas. Here, again, by cutting the shoots that have flowered back nearly to the base at any time during winter or early spring a full season of growth is left for new wood to be made that will flower when the time comes round again.

For the remainder of shrubs grown on walls, those, that is, which blossom on the previous year's growths, but too late to be pruned as advised for March and April flowering ones, a process of thinning must be adopted. A shrub that blooms in early May, especially if late in starting growth, may sometimes be shortened back generally, but those that flower in late May and in June on the previous season's wood cannot, as a rule, be pruned in that way. If it is done early enough

Digitized by Google

to leave an entire season for growth, a crop of blossom must be largely sacrificed; if it is done after flowering, the time for new growth is very much reduced and the succeeding crop of flower correspondingly so. The thinning consists in cutting out, or shortening back, branches standing out too far from the wall and in removing branches that have become stunted, worn out, overcrowded, or are in any way unsatisfactory. This should be done as soon as the blossoming is past. At the same time any gaps should be filled and thin places strengthened by "laying in," *i.e.*, tying back, new wood to the wall.

Walls 8ft. to 10ft. high are not very suitable for true climbers of strong growth, like wistarias, tecomas or celastruses. For them the walls of dwelling-houses or other buildings are better, where there is loftiness and greater space. Such climbers have a strong tendency to become devoid of growth at the base and form naked stems, thus leaving the lower part of the wall unfurnished. Where they are used it is a good plan to plant ordinary wall shrubs in addition to cover this lower part with vegetation, leaving the upper part for the climbers. Even less vigorous climbers, like clematises and jasmines, have the same tendency to make for the top of the wall, and it is well to associate tender shrubs of more sturdy habit with them also. For walls 10ft. and upwards high true climbers and ordinary shrubs may even be planted alternately. In fact, any vacant spaces at the lower part of the walls may be furnished with the dwarfer shrubs.

The following are notes on a somewhat comprehensive list of shrubs which may be treated as wall plants:

ABELIA.—The strongest growing of the abelias is A. grandiflora, a hybrid between chinensis and uniflora, usually grown in gardens as either "chinensis" or "rupestris." It is a useful wall shrub for filling spaces up to 5ft. or 6ft. high. It is evergreen, with smallish, lustrous, dark green leaves and pinkish flowers continuing to develop from July to October. Other species that can be used for covering low places on walls are Schumannii, longituba and the Mexican A. floribunda, whose tubular, rosy red flowers, 1½ins. to 2ins. long, are perhaps the most beautiful of the abelias.

ABUTILON VITIFOLIUM.—Except in the warmest counties this must have wall protection. It is really a small tree, and is best adapted for a high wall or house front. It may be used to fill a narrowish space between windows. The flowers, which resemble those of a small single-flowered hollyhock, are 2ins. to 3ins. wide, pale purplish blue in the typical form, pure white in var. alba. They open from May to July.

ACTINIDIA.—Wilson's introduction, A. chinensis, is almost too rampant for a wall. I have never seen it so beautiful as in Mr. Gerald Loder's garden at Wakehurst, where he has planted it to form a tangle against a low building whose roof it partly covers. When I saw it it was laden with white flowers which afterwards turn buff-yellow. A. Kolomikta is worth growing for the remarkable colouring of the foliage, the leaves becoming, as the season advances, partially or wholly pink or pinkish white. Both these are hardy and deciduous, and can be grown in the open on supports.

THE BLUE-FLOWERED ABUTILON VITIFOLIUM WHICH FORMS AN EXCELLENT SUBJECT FOR WALL DECORATION.

ADENOCARPUS DECORTICANS.—A brilliant member of the broom family which needs a sunny wall to show its best. The flowers are rich golden yellow, very abundant, and open in May and June. Suitable for a wall 6ft. high.

AKEBIA. — The two akebias, A. lobata and A. quinata, are vigorous twiners and, being deciduous, quite hardy and self-supporting, are better fitted for climbing over a decrepit small tree than for a wall, where, nevertheless, there is a better chance of their developing the remarkable violet-coloured, sausage-shaped fruits.

ANTHYLLIS BARBA-JOVIS (Jupiter's Beard). — An evergreen of the broom family suitable for a wall 6ft. or so high, where its small, silvery grey, pinnate leaves and rounded heads of pale yellow flowers are quite attractive.

APLOPAPPUS ERICOIDES.—A very distinct, shrubby composite with very numerous heath-like leaves and crowded clusters of yellow flowers opening on the current season's growths in August and September. Grows about 5ft. high, evergreen. California.

ARAUJIA SERICOFERA.—Perhaps better known as Physianthus albens, this vigorous climber needs a wall, even south of London. It is suitable for a lofty wall, towards the top of which it may be allowed to form a tangle of growths. The flowers are white, fragrant, 1in. or rather more wide.

ARISTOTELIA MACQUI.—Without any great attractiveness in blossom, this vigorous Chilean shrub may be used where a dense evergreen covering for a shady wall is desired. It may even be tried on a north wall. The leaves are dark lustrous green, ovate, and average 3ins. to 4ins. in length.

AZARA.—The well known A. microphylla, although it was killed to the ground by the great frosts of February, 1895, at Kew (but never since) may be considered as practically hardy in the London climate. In the north-eastern counties it will probably need a wall, and this, by reason of the grace of its shoots thickly set with the tiny evergreen leaves, and the fragrance of its flowers in early spring, it well deserves. In the south, A. Gilliesii, with much larger shining leaves, certainly needs wall treatment.

(To be continued.)

NATURE'S ROCK GARDEN

AS I have described elsewhere in these papers, our limestone Yorkshire dales are in many parts one fine succession of rock gardens. Planned by Nature on the grand scale as regards crag and deep-fissured boulder, they give shelter to broods of small plants that nestle like children in a giant's embrace.

Some of these plants are not beautiful because they are rare, but rare because they are beautiful. This has a cryptic sound, perhaps, but it is the very gist and kernel of the plea that many of us wish to make.

So much depends on the way a crying grievance is made clear to delinquents who sin gaily and without thought. Suppose the usual brigand of our dales was left to wander, alone and unwatched, along the paths of a private rock garden. It would never occur to him to stump up such roots as took his fancy. If a fellow of the baser sort companioned him and prompted such petty theft, he would recoil from the suggestion. He would explain that the plants were another's property, and would probably draw a forceful picture of the owner's desolation when he found his garden ravished of its charm.

It is different altogether when this same moralist is let loose among our highlands. Nature has built and planted and tended here; so he is free to plunder as he lists. We'll not labour the point that Nature sorrows with a gigantic human sort of grief when her nests of flowering plants are spoiled. It is not a whit less true, and simpler to explain, that the owners of these highland gardens will be desolate, too, when they come to see what has happened.

The owners are those countless hosts of people who, by circumstance, cannot afford rock gardens of their own—people who live in the country, loving its every charm of flower and shifting weather, or folk whose recreation and delight is to escape from the soot-laden streets into a larger air. They come to a wooded dingle, where the primroses rioted among the mossy boulders last year; and no laughing, dew-wet eyes glance up at them. The plants are dying, somewhere in a hapless garden befogged by soot and chemicals; and the few who stole are getting nothing at the price of a ruined glen.

There were cowslips once on Kirth Brae, which looks down on Wharfe River, queen of our northern streams. They donned their gold-laced livery when the summer of their pride arrived, and curtseyed to the dancing breeze. Now there's nothing but a bluff of sheep-cropped pasture. Cowslips and primroses grow rare among us, and our loathing of freebooters takes clearer shape.

We should be more free from marauders higher up the dale. So we are, in a sense. But one spring day a car halted at the edge of a woodland that roamed up into a clearing fit for Titania and her revels. The daffodils had bloomed in readiness. Oberon was sleeping beside his bride, till night and the moon arrived. The fairy-sort were slumbering, too.

When the good company awoke, not a daffodil was left to give them cheer. The pages of their bridal dance had all departed, and their feet lagged as they tried to tread a measure. And next day, when lovers of this special haunt roamed out to see the daffodils, their hearts were sorry.

There's little farinosa, too—the primula that roves in happy billows of rose-pink among the circling rocks. They are raiding her haunts, and nothing we can din into their untutored, urban wits will persuade them that the flower will sicken and die in the alien prisons they name gardens. You can find her in plenty still, thanks to the steepness of hills that daunt her ravishers; and she is one of our plants that will survive, I fancy. She is prolific, full of courage, and can adapt herself to the wild vagaries of our weather; but to carry her captive into the towns is to break her heart and spirit. So, on this practical count alone, we plead with would-be brigands to leave her, bonny and undismayed, in the mountain home she loves.

The globe flower, too, grows rarer in our midst. Her charm is evident, of course, when her golden bells ring up the good June weather. She is, perhaps, the belle of all the wonderful buttercup family. So people come and dig her up in spendthrift quantities; and she, like farinosa, pines to death in exile. A picture comes to mind of a certain hollow in a certain wood—a moist, wide clearing between squirrel-haunted trees—where the globe flower riots. Nothing can explain, except actual vision, the midsummer blandishment of that hollow. The mossy turf, the slant, cool shadows of larch and rowans across the golden flowers, make up a picture that almost touches sadness because of its young, glowing loveliness.

That special hollow is unrifled still, though it lies near one of our dale's villages. When strangers who have heard of it come asking for direction, they are given a route that leads them at the finish to what is known locally as the "back-end of nowhere," and they return, fuming at our craftiness. They say we are secretive. We are; but it is they who have made us so. When thieves approach, wise folk hide their precious jewels.

They have made us combative, too. Heaven knows how loth men are these days to ask new laws for a country drenched to the marrow with legislation; but one more is needed. Wild birds are protected in our midst. The plover especially are free to nest, unhindered by the needs of epicures. Ancient buildings are protected. Why should the most helpless of fair, English things—the wild flowers—go still unsheltered by the law?

There are two types of plant hooligans. One is the professional thief who simply takes everything useful that comes to hand and sells it for profit. The other is a covetous sort of amateur who thinks himself a flower-lover. He, too, grubs up everything in the mass, to misplant in his own garden. For these no persuasion avails, no argument. Their only hold-back from crime is a vision of handcuffs rampant on a field of wild flowers azure.

To other bandits of more tender conscience I would explain what happened to the lady's slipper high up our dale. It was never common among us. Such beauty could not be. But it was not rare. Everybody knew where sequestered clumps were to be found, and each summer they pilgrimed to its haunts—not to rifle, but to wonder and appraise. It was, as you might say, a mystical plant, reverenced as something apart from usual flowers.

Then ruffians found out her haunts, and came by stealth. They were like the big criminals who steal diamonds only and pass trinkets by. Clump by clump the lady's slipper went to die in exile, sold to an abhorrent slavery, till we could count only three to cheer us with remembrance of the elder days.

It was about this time that strangers, housed in farmstead or tavern, chided us for our indifference to the beauty of our land—especially the beauty of its flora.

We encouraged their belief in our bucolic disregard of the beauties surrounding us. Queries were met for the most part by stolid ignorance, though some preferred the "back-end of nowhere" method already mentioned, and diverted attention from the three sanctuaries by suggesting plausible, long routes across the fells. For all that, two plants of the lady's slipper went in one season, and next year the third.

I happened to be up-dale that summer, staying at a fell-side inn, and a thing near the heart of sorrow arrived. Through the rosy gloaming that softened limestone screes and pine woods and the dusty road, an oldish man stepped into view. As he reached the old lang-settle that did duty for a seat outside the inn he hesitated for a moment, then dropped into place beside me.

He was weary and distraught. For awhile he sat there, gazing out into the dusk. Then he turned.

"She's gone," he said.

He was so lost—so stunned, somehow—that I could only fancy he had gone through bereavement of a tragic kind. I waited, and presently he opened out his grief.

"Forty years I've come to the dale, just for the joy of seeing her. Nobody else knew where she lived, I thought. And now she's gone."

Then by and by I learned that he was talking of lady's slipper, the last of her race, and it was all curiously moving. A lover bereft of his mate might have shown the same still, rudderless grief. Forty years of constancy to this one pilgrimage were ended.

He got up presently, and glanced at the misty fells "It's good-bye," he said. "The dale will mean nothing to me without Lady Fair."

Digitized by Google

The sound of his footsteps, tired and slow, faded out to silence, and I sat on, wondering if men would ever learn that such as Lady Fair were meant to stay among their mountain fastnesses.

If we have found another clump of lady's slipper since that day, I will tell you exactly where to find her. Any large-scale map will show you the Yorkshire mountains — Ingleborough, Whernside, Penyghent—with great spaces in between, gashed by swart ravines.

It is a big country, hard to explore even for its intimates; and somewhere in it Lady Fair blossoms every summer.

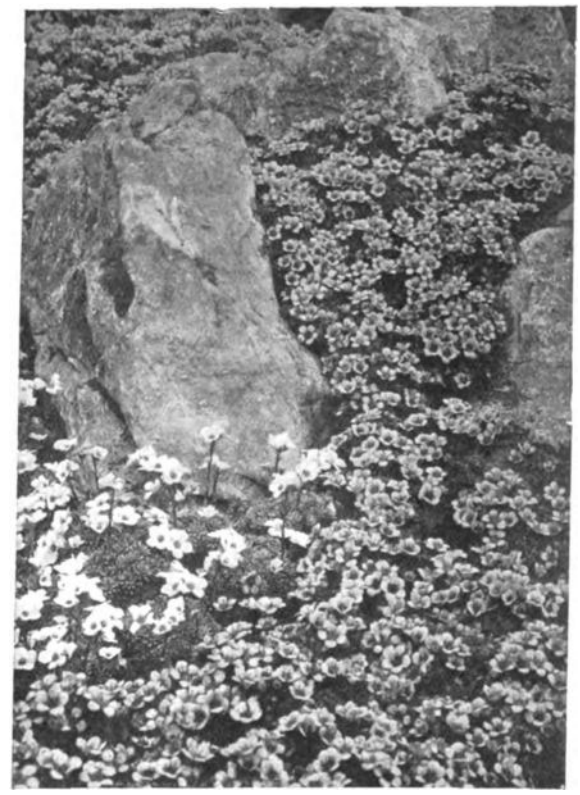
HALLIWELL SUTCLIFFE.

SAXIFRAGES IN GENERAL

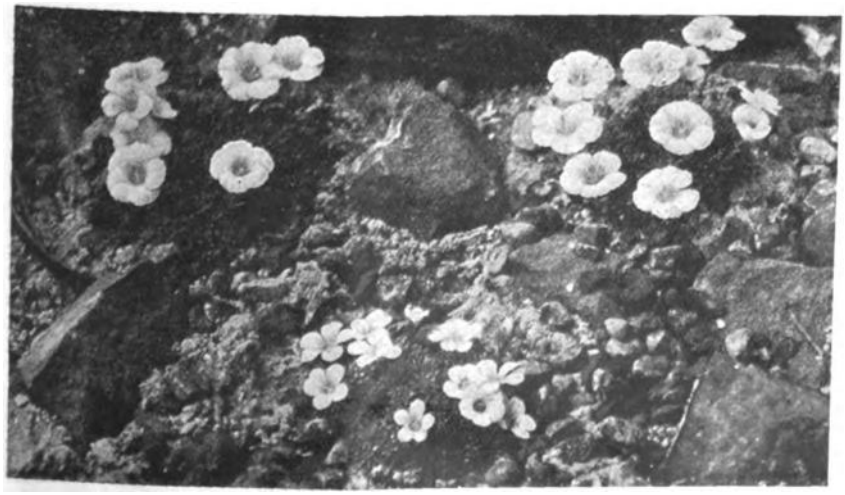
BY DR. R. LLOYD PRAEGER.

TO have to write about the Fifty Best Rock Plants was bad enough, but now the Editor invites a contribution on a more ticklish subject, namely, the Fifty Best Saxifrages. It would seem to be worth while to probe, in the first place, into the whole subject of the saxifrages and to get some general ideas as to the length and breadth of this large and complicated genus before attempting to make a selection for gardens. That it is large enough and complicated enough in all conscience one can see by dipping into the recently published monograph of the group by Engler and Irmscher. This runs to over 700 pages, which by itself speaks volumes. The index, which includes the names of the species and varieties, including their synonyms, contains some 2,800 names. The authors admit 305 plants to the rank of species, and each species has anything from 0 to 100 varieties, sub-varieties, forms, sub-forms and hybrids. Heaven defend us from such an appalling horde! Their native habitats spread over an extensive region, from the high Arctic down to Abyssinia and the Andes, being grouped especially about the mountain ranges, and they vary in height from half an inch to six feet, and their flowers display all the colours of the rainbow—except blue. While many of them are quite distinct and easily identified, others form complexes of closely allied forms of an intricacy unsurpassed among the flowering plants.

It is with some relief that one finds that they can be subdivided into groups. Engler and Irmscher distinguish fifteen such, many of them possessing well marked distinguishing characters. These groups vary much in size—from a single species up to eighty-eight species, to be exact—and while some have a definite geographical location, others are very widely spread. What will interest readers of THE GARDEN most will be the relation of these groups to the plants which are useful for garden purposes—for in the rock garden saxifraga stands head and shoulders above any other genus in importance. We find that the species which are worth growing, and which consent to dwell in our gardens, are distributed most irregularly among the sections of the genus. The largest section of all — Hirculus, with eighty-eight species — yields practically nothing to the horticulturist, consisting as it does mainly of small and not showy herbs of wet places mostly in the north. The next largest group — Boraphila, with sixty-four species—is almost equally unproductive of plants for the garden; the British S. stellaris and S. nivalis give a good idea of the type of plant included in it. In the third largest group—Dactyloides, forty-nine species—we at length arrive at plants familiar to the gardener. Here belong all the "mossies," and it is noteworthy that this is the only group of the saxifrages, the garden value of which has to any great extent been improved by the plant breeder, for the grand range of "red mossies" are a garden creation of recent years. Some of the garden forms of the silver and kabschia saxifrages are certainly very beautiful, it will be admitted, but they are almost all simple crosses, and do not represent nearly so remarkable a break-away from the natural forms as do the "red mossies." Next in order of size of group, and first of all in horticultural interest, comes Kabschia, with forty-five species. This is a high mountain group, of which only a certain number will condescend to dwell in our low-level gardens. Many of the most remarkable or daintiest of them all, such as S. imbricata, S. quadrifaria and S. subsessiliflora, never have been (so far as I am aware) and probably never will be in cultivation, for they come from 10,000ft. to 15,000ft. in the Himalayas, and live in a climate hopelessly different from ours. In this group the hybridiser has been particularly busy, and endless "new" plants, mostly under names by no means euphonious, tempt our eye in catalogues. But very few of these hybrids are better than their parents, and only a saxifrage maniac will be



DRIFTS OF SAXIFRAGA OPPOSITIFOLIA LEND COLOUR AND CHARM TO THE ROCK GARDEN.



S. FALDONSIDE IN COMPANY WITH S. BOYDII, A CHARMING PAIR OF KABSCHIA SAXIFRAGES

Digitized by Google

tempted to order them indiscriminately. But be it admitted that there are a few—mostly with reassuring British names, like Boydii and Irvingii—that are among the very best of Kabschia saxifrages.

Passing by Nephrophyllum (nineteen species), which includes the well known S. granulata, but little else of garden interest, we reach the important group of Euaizoonia, the charming silver saxifrages, only ten species strong, but with varieties and hybrids yielding a host of delightful rock plants, from the noble S. Cotyledon to the tiny S. valdensis. And one feels a special kinship with this group, since they are essentially plants of the mountains of Europe, and they recall (to such of us as have been lucky) visions of delightful expeditions through the Alps and Pyrenees and Carpathians.

THE NOBLE S. COTYLEDON OF THE SILVERY GROUP.

The Diptera group (nine species), on the other hand, are easterners, and mostly far-easterners; and in the pleasing form and colours of S. sarmentosa and S. Fortunei we recognise the peculiar charm which is the inheritance of the flora of Japan and China. The remaining eight sections of saxifraga number only twenty-one species between them, no section possessing more than three or four members. Three of them alone are of horticultural importance, and all are quite in the forefront. These are Robertsonia, which consists of the invaluable London Pride and its allies S. Geum and S. cuneifolia; Porphyrion, which gives us the lovely S. oppositifolia and its cousins S. retusa and S. biflora; and Xanthizoon, which contains a single species, S. aizoides.

To come back to our text—the fifty best saxifrages—we can now see at least from which sections of this large and varied genus they are to be drawn. They will consist of three main groups—"Silvers" (Euaizoonia), Kabschias and "Mossies" (Dactyloides), with some of the few but precious Dipteras, Robertsonias, Porphyrions and the single Xanthizoon added on. Our next duty will be to make a selection from among the very large number of beautiful forms—species, varieties and hybrids—that even this reduced assemblage of saxifrages offers to us.

IMPRESSIONS OF SOME OF THE NEWER AND BETTER GLADIOLI

(*Continued from page* 141.)

AMONG the large-flowering hybrid varieties, the following will be found to give every satisfaction in the garden.

A. B. KUNDERD.—A ruffled or frilled petalled variety. Ruffled gladioli are a fairly recent development and by many considered less formal than the plain petalled types. In sweet peas, the frilled petalled or "Spencer" type quickly ousted the "grandiflora" or plain flower. One wonders whether this will again be the case with gladioli. A. B. Kunderd is a beautiful cream, tinted pink, with cerise lines on its yellow lip. At it best, very lovely indeed, but, in my opinion a tendency of the colour to "run" will prevent its becoming one of the "stars."

ADELAIDE DE LUXEMBOURG.—Of Dutch origin. A good and very strong-growing gladiolus which will be a favourite with many. Pink with white and yellow centre.

ANNA EBERIUS.—Another which can safely be predicted to become very popular on account of its remarkable purity of colour. Quite a distinct shade of lavender-purple with deeper purple throat. Mixed with the light creamy pink or cream shades, it makes a very charming decoration.

BLERIOT produces a very fine spike, is strong growing, large flowered and brightly coloured. Apricot rose with a rich orange throat.

BYRON L. SMITH.—Its colour is reminiscent of a cattleya orchid, a very beautiful lavender pink with cream throat blotch. Very distinct and undoubtedly destined to become a great favourite.

BLUE CELESTE.—There are many so-called blue gladioli, but I feel sure that, when better known, this soft yet clear violet blue will be a firm favourite with many. A free grower and (for a blue) of fair size. It originated in Holland.

CATHERINE COLEMAN.—A beautifully made spike, large bloomed and delightfully coloured. May best be described as a rich shell pink. A gladiolus which has very greatly pleased me.

CLEAR EYE.—Bright scarlet with a clear-cut pure white blotch. A bunch is very distinct and attractive, and I consider it a great improvement on the older and better known variety, Princeps.

CRIMSON GLOW.—Perhaps the best description one can give of Crimson Glow is that it is a much richer and more brilliant Red Emperor. It is the richest crimson I have yet seen, large-flowered and a strong grower.

DR. F. E. BENNETT.—This variety has come to stay. The massive, well made blooms of fiery red are well placed on the spikes and, further, many are open at the same time. One I can recommend all to try with every confidence that it will not prove disappointing. As yet, it is, perhaps, rather expensive but I include it in this list.

DR. W. VAN FLEET.—This is of rather unusual shape and colour, but extremely beautiful and very distinct. It somewhat resembles Mrs. Dr. Norton, but is, in my opinion, a much better variety, both for freedom of growth and colouring. A charming blending of delicate rose pink, deeper at the edges of petals, with a canary yellow throat.

E. J. SHAYLOR.—Just a little disappointing, not as regards its colour, which is a rich rose pink, but, for my taste, not a sufficient number of blooms are open at the same time, and, although a strong grower, many of the bulbs contracted disease and were useless.

EMILE AUBRUN—This unique coloured gladiolus has pleased me as well as any I have seen. The blooms are very large indeed and form a perfect spike. Its colour is very hard to convey in words, and the best I can do is to term it a mixture of copper, slate and cherry, somewhat similar but warmer toned than the border carnation Grey Douglas. This is another one feels sure will become popular.

ENERGIE.—A very handsome and extremely well made and compact spike, well worthy of a trial. The colour is blood red.

EVELYN KIRTLAND.—A beautiful salmon rose pink, shading to shell pink in the centre, with bright red blotches on the lower petals. Although Evelyn may be one of the most lovely

Digitized by Google

varieties ever raised, it has the fault of rather a weak stem and must be staked.

GOLDEN MEASURE.—Briefly, this is the best and richest golden yellow large-flowering gladiolus. It makes a magnificent spike, growing 5ft. tall under favourable circumstances.

JACOBA VAN BEIREN.—Another extremely strong grower, a nice large bloom of soft purple. It will have its adherents, but I prefer the deeper toned Anna Eberius.

MAJESTIC.—Orange pink hardly conveys the wonderful glowing, yet soft, colouring of Majestic. There is something else suggesting the bright soft orange of the begonia. For colour alone, it is superb; but it must be confessed that its growth is rather on the weak side. In spite of this, I expect Majestic to become popular.

MARECHAL FOCH.—This is one of the varieties of the noted American raiser, Mr. Kunderd, and must not be confused with the Le Maréchal Foch of Dutch origin. It is a very valuable large-bloomed gladiolus, giving an extra fine spike, and is sure to please if given a trial. A salmon pink with rich red blotch.

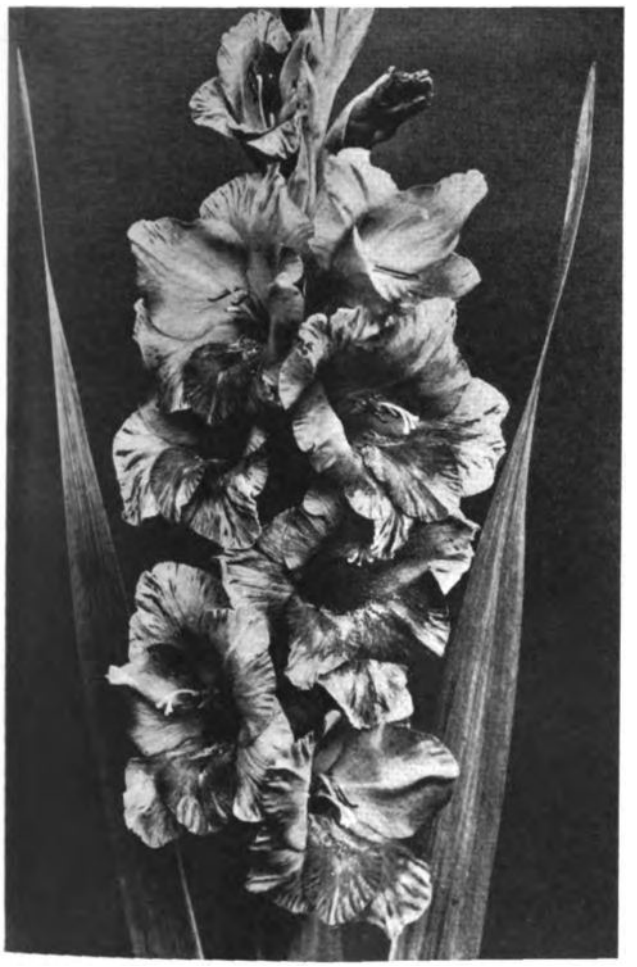
MRS. F. C. PETERS.—One of the best gladioli in existence. A very vigorous grower, giving a perfect spike of the largest size blooms. Its colour is a glorious lavender blue on a white ground. Whatever one's taste may be, Mrs. F. C. Peters will be considered to form one of the best dozen varieties by nine out of ten who grow it.

MRS. H. E. BOTHIN.—Another of ruffled or frilled type. A strong grower, most distinct, of flesh salmon pink colouring with flame scarlet blotch. Although really valuable, one would like to see more blooms open on the spike at the same time. This is its only fault.

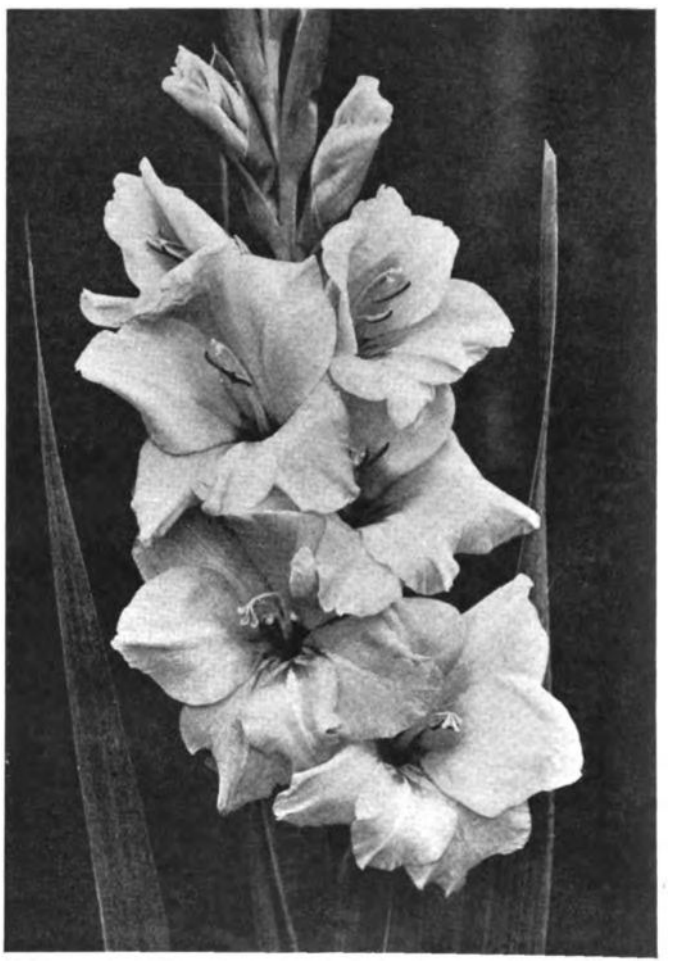
MRS. LEON DOUGLAS.—A giant gladiolus, taller and stronger growing than any others I have ever seen, it towers above them all. The ground colouring is begonia rose, slightly striped flame, with a lemon lip lightly speckled with ruby. Although the individual blooms are not as perfectly made as one would wish, the size of the spike and bloom are sufficient to compensate fully for this fault.

MRS. VAN KONYNENBURG.—This is the best light blue gladiolus I have yet seen. A beautiful and distinct colour and a good grower.

MRS. W. H. PHIPPS.—In my judgment, here we have one of the very best gladioli in existence. Its truly wonderful colour is hard to describe, perhaps impossible accurately to convey in words. It has to be seen to appreciate fully its real worth. La France pink, overlaid light rose salmon, the lower petals striped and speckled with ruby, rivalling the begonias in richness and beauty of coloration. From nine to ten large blooms are open at once on the well made spike, grown naturally. It is, at present, rather high priced, but if this debars a trial this season I advise my reader to jot down the name, for it is a variety all growers will obtain sooner or later. One spike is a bouquet in itself.



THE HANDSOME SPIKE OF PURPLE GLORY.



THE BRIGHT ORANGE RUFFLED BLOOMS OF ORANGE GLORY

ORANGE GLORY.—This is a ruffled gladiolus which has somewhat disappointed me, not by any means on account of its colour or form, but my experience of Orange Glory the past two seasons has been that not more than 50 per cent. of the corms produced a flower spike. This may not, of course, be general. It is a vigorous grower and a glorious bright orange colour.

PAINTED LADY.—A meritorious English-raised variety, very distinct and beautiful. The colour is snow white with a clear-cut and well defined red blotch. Striking and very good.

PINK WONDER.—A fine novelty with large massive-looking blooms. Clear light rose pink with deeper rose lines in the throat. In my opinion, one of the best in the pink shades.

Digitized by Google

PRIDE OF HAARLEM.—A Dutch introduction which has greatly pleased me. The colour is very distinct, a soft cherry rose. Large flowered and a nice spike.

PURPLE GLORY.—One of the "stars." A wonderfully strong-growing ruffled gladiolus with large, well shaped, velvety purple-maroon flowers, having almost black blotches on the lower petals. A grand variety which will most certainly become first favourite in its colour class directly its price is a little easier.

RICHARD DIENER.—Very refined in general appearance. A lovely pure shade perhaps most accurately described as geranium pink, with a sprinkling of ruby on its creamy yellow centre. Almost certain to please all tastes.

ROSE PRECOSE.—In my opinion, this is one of the very best varieties which Holland has ever produced. The spike is well made with a fair number of florets open at once, while the colour is exquisite—salmon pink feathered light red. A most charming gladiolus which all should try.

VEILCHENBLAU.—For colour alone, the finest blue I have tried, a glorious viola blue. Its constitution, apparently, is rather weak, and it is a difficult propagator. For these reasons, it is not likely to become very cheap.

VENUS.—This will appeal to all who like the delicate shades. Venus is very dainty and attractive, an early bloomer, of a light silvery rose colour with creamy white lower petals. It has only one fault: its stem is a little too weak; but, really, its good qualities outweigh this, and I can strongly recommend it.

SAPHO.—Here is a colour quite out of the ordinary run, very quaint but still very beautiful. It will not be everyone's favourite, but will strongly appeal to any who prefer something uncommon. The colour combination is brownish red, feathered steel blue and purple. C. H. A. S.

MORE SOUTH AFRICAN GLADIOLI AND THEIR HAUNTS

THE PREVIOUS ARTICLE ON SOUTH AFRICAN GLADIOLI, WHICH APPEARED IN "THE GARDEN" LAST YEAR, CREATED SO MUCH INTEREST THAT WE ARE PLEASED TO PUBLISH A FURTHER CONTRIBUTION ON THESE BEAUTIFUL FLOWERS.

THE gladiolus is undoubtedly the flower of 1926, and it seems to express the spirit of the age more vividly than any other flower. Intensity of colour and life—success—is written large on its glowing loveliness. Success which may in time appear somewhat blatant, for all is expressed, nothing suggested, in the florist's gladiolus to-day. But this is not the case with their wild "colonial" cousins blooming among the mountains of the Cape; their dainty grace brings back to us the wind-swept rocks among the clefts, and crannies where they find a home.

A warm day in early summer finds us climbing the lower slopes of the Drakenstein mountains, and when we at length reach the top of a ridge to rest and admire the wonderful view — behold! clumps of Gladiolus cuspidatus between the rocks on every side! Only about 1½ft. to 2ft. high, but the blossoms the loveliest deep cream with the typical Painted Lady markings on the lower perianth segments in deepest carmine. The colour effect is also greatly enhanced by the anthers showing a soft powder blue against the rosy cream throat. The plant seems to improve under cultivation, the flowers get larger every year, and the colour a deeper cream, almost yellow.

The ordinary Painted Lady, or G. blandus, is the best known among European and American hybridists. This one we consider very ordinary, a sort of "country cousin" among pypjes, as we call them in our familiar fashion. G. blandus is the most common, perhaps that is why we esteem it least, but compared with the others it is clumsy and thick-set. The leaf is wide, the stems are thick, the flowers set close together, "stodgy" we call it, though I expect did we not know the others we should admire it greatly.

GLADIOLUS BLANDUS.

The one we treasure most is the pink bell, or G. inflatus, and anyone who has fallen a victim to its daintiness will not give a second thought to blandus. Its stem is as fine as a harebell's, which species it suggests in every way, only the blooms are very much larger, much more open and of a clear distinct pink with indescribable carmine markings. It grows about 1½ft. high, with two and sometimes three blooms on a stem. A quantity of these flowers in a large crystal glass bowl was a sight I shall never forget. But, alas! every rose has its thorn. There must be some reason why these do not appear in the nurserymen's lists and only as treasured specimens in our gardens. They grow in the most inaccessible spots on the mountains, and when, after days of climbing, one has the good fortune to come on a patch of them they are almost impossible to dig out, the ground is hard and the corms grow at a most unconscionable depth. However, we had the good fortune this year to hunt down a patch of them in seed. Now we await results.

The kalkocutje, or G. alatus, is quite a distinct type, unlike any of the others. It comes in the spring on the edges of the cornfields and vineyards, and it is always greeted with joy. The blooms are a peculiar terra-cotta shade. The books mostly give them as "red," but this does not in the least describe them. The shade is brighter than terra-cotta, and yet not in the least orange. This is shown up by brilliant green shading in the centre of the flower and yellow markings on the lower segments. Only about 1ft. high, with wide leaves, it seems very different from its relations. The children never call them pypjes. Surely a type that should be useful to the hybridiser, particularly as it has a very sweet scent.

G. grandis and G. tristis are better known, and are often spoken of as one and the same, though very different both in appearance and habit. G. grandis grows about 3ft. high on a thin, delicate stalk which supports one large and very attractive bloom. It is difficult to say what is the colour of the latter. The background is probably cream, but in the specimen I have there is no background to be seen, the entire bloom being covered with brown dots and markings, reminding one somewhat of the markings of Fritillaria Meleagris of the Suffolk pastures. But it varies very much. Some people describe the flowers as cream with crimson or brown blotches, but through all its variations it is extremely attractive. The blossom is very wide and the edges of the segments wave and curve in every direction. A thoroughly unorthodox denizen of the veld, one finds it quite unexpectedly here and there in moist situations.

G. tristis is more common. Walking home on a summer evening after sunset by a sluit, or marshy waste, one will suddenly get a whiff of a most delicious scent, and the pale yellow flowers of tristis, or the avondbloom, will be found gleaming among the tall reeds. It grows to 5ft. with fifteen or more large blooms

Digitized by Google

on its reed-like stem. The *upper* segments are marked with brown, while the lower segments have the markings only on the outer or reflex side of the flower. No wonder it was among the first to be cultivated. One can picture the long summer evenings in England when one sits in the garden in the dusk. What joy one would find in clumps of these tall yellow beauties opening to scent the night air with perfumes from the veld!

There are many, many more, some of them better known than these. For example, the beautiful Caledon bluebell, G. spathaceus, so hard to get; cardinalis, which sends out its long sprays to trail over pools and mountain streams; the dainty G. gracilis, which comes in the springtime in delicate shades of blue, mauve and yellow; and G. recurvus, somewhat bigger and sweetly scented. And for years we may go on finding new ones and growing more and more, enchanted with their beauty.

With regard to their cultivation we have much to learn, but we are learning. In cultivating, the chief thing to remember

G. SPATHACEUS. G. GRANDIS.

is that most of them do their growing in the winter and rest during the hot, dry summer months after flowering. They should therefore not be taken up and stored, but must be protected when the winters are severe. Here they get no frost, but a very wet winter when they do most of their growing; therefore if they are taken up after flowering they must be replanted in the autumn.

When grown from seed most of them flower the second year. The tiny seed bulbs must never be stored. One curious fact in the history of South African gladioli is interesting—they are entirely disregarded in their native country. A handful of enthusiasts are trying to protect them and to save them from extinction at the hands of ruthless flower-sellers, but nine-tenths of the population know nothing of their existence, and while they have some pride in the wonderful South African proteas and heaths, the pypjes interest them not at all, though no doubt they will buy them for their gardens when they come as expensive imported bulbs.

K. C. STANFORD.

THE DAINTY PINK-FLOWERED G. INFLATUS.

THE KALKOCUTJE, OR G. ALATUS.

PRUNING BEDDING ROSES

THE time has now come when hybrid perpetuals and, in the southern counties, hybrid teas, may be pruned. A great deal of the bad pruning which one meets is due to badly thought out planting. Selection only by colour and quality and quite regardless of habit will place a bed of Hugh Dickson, for instance, between Mme. Ravary and Ophelia. To prune Hugh Dickson as it should be pruned gives a most uneven immediate effect, and this unevenness is accentuated throughout the season. Hugh Dickson is a robust and excellent rose, but it is not suitable for bedding, and the same remark applies to many other strong growers. Frau Karl Druschki comes to mind as a flagrant instance of a rose quite unsuitable for bedding in association with other varieties, and it is very doubtful whether even that old favourite Caroline Testout is not too tall for the purpose, as well as the salmon pink Joseph Hill. Neither of these varieties lend themselves to pegging down—a course which may generally be adopted with the hybrid perpetuals.

Now, as regards the actual pruning of bedding roses which, if well selected, will almost certainly, with the possible exception of Lady Hillingdon, belong to the hybrid tea and Pernetiana sections. All dead and unripe wood should first be removed. This latter will very probably be the thickest wood in the tree, being strong wood thrown up from the base late in the season. It corresponds roughly with what in fruit trees are called "water-spouts." Any unduly thin wood had better be removed at the same time. The careful pruner will now take a survey of the tree before he commences to prune, since in bedding roses the shapeliness of the tree is an important consideration. Having selected six or eight shoots (if there are so many), which are quite sound and healthy and which leave the centre of the tree a little open, they should be cut back to from four to eight eyes of the base from which they started, always bearing in mind that the weaker the tree, the harder it should be pruned back.

The Pernetiana varieties are invaluable owing to their colouring, but it is wise not to employ them for bedding more than is necessary, as they rather resent hard pruning and, under bedding conditions, are not long-lived. Perhaps the newer sorts will not suffer in this way as much as did those first introduced; but even the universally and deservedly popular Mrs. Wemyss Quin is not free from this defect. It is far stronger and happier when allowed to develop into a large bush. The following recognised bedding varieties call for hard pruning—to say, four or six eyes from the base of the shoots: Augustus Hartmann, Château de Clos Vougeot, Geo. C. Waud, Mrs. C. Russell and Richmond.

The pruning of the dwarf polyanthas, so popular now for bedding, is for this purpose very similar to the H.T. and T. sections, except that, as they are thin growers, more shoots may be retained and these cut over quite close—within two or three eyes of the base. This will give the dwarf effect generally worked for. If there is no desire to keep them down, little pruning need be done other than the removal of the spent (and eyeless) last season's bloom trusses. This pruning may now be proceeded with.

Since some people like pegged-down roses, it may be well to explain the process, which certainly goes far to obtain new wood from the bottom. This, incidentally, where pegged and naturally grown roses are associated together, always forms a young forest, far taller than the vegetation in the other beds. For pegging-down, then all old wood should be cut away and the one-year shoots left almost full length, right up to where the wood thins seriously or to where the buds have broken excessively, should this be lower than the thin wood. Tarred string is used for securing the growths to the notched pegs, which should be long enough when driven in to hold securely. About a foot is the usual length, but much depends upon the character of the soil. In some soil 9in. pegs hold securely, in others it is almost impossible to persuade a peg to hold. Tie the string to the peg first and arch the shoot over to meet. If any attempt is made to lay the shoot along the ground it will snap off at the base.

NOTES OF THE WEEK

ERODIUM CHRYSANTHUM.

TO those who know the plant, it is a matter of some surprise that Erodium chrysanthum is not more general in cultivation than it at present seems to be. A native of Greece, it is, as erodiums go, hardy enough in this country. By the colour of its flowers, which are of a deep primrose hue, it is readily distinguished from the other members of the genus. It flowers most profusely throughout June and the much divided silvery leaves add to the attractiveness of the plant.

The plant is seen at its best when growing in a sun-exposed pocket in the rock garden, the growing medium to be kept open and porous by the inclusion of a fair amount of sand and small gravel.

It is best increased from cuttings taken at the end of July, these cuttings to be inserted, four or five round a 3in. pot containing sand, which pots should be plunged to the rim in sand in the cutting frame.

The frame should be kept moist by light sprayings at intervals, always remembering to have the shading handy. By having the cuttings in pots it is convenient to lift the pots occasionally and look for any signs of roots, whereas, if the cuttings were dibbled in lines across the frame there would be the risk of an over-anxious propagator snapping off young roots in his attempt to ascertain whether or not the cuttings were rooted. The cuttings should be potted off singly as soon as they are rooted, placing them back for the first week or two to the shelter of a covered frame and gradually hardening them off. For the winter, plunge the pots in a cold frame, removing lights on suitable days. Plant them out on the rockery in the spring.—W. H.

FIGHTING CABBAGE PESTS WITH SALT.

SOME interesting experiments have been recently carried out in connection with the fighting of cabbage pests. A close examination of large numbers of wild cabbage plants, which are often found growing close to high-water mark in soil that is saturated with salt and where its foliage must be repeatedly drenched with spray, has revealed the fact that these are hardly ever attacked by caterpillars or grubs of any kind. Pests placed on the wild cabbage leaves speedily deserted them for something more palatable. The reason for this is that insects of all kinds have the greatest dislike to salt. Cabbage plants in gardens treated with salt will show a remarkable freedom from the attacks of pests, although specimens in adjoining plots are badly affected. A moderately strong solution of salt and water may be sprinkled on the foliage with the best results, as this will not harm the plant in the least. A further protection against ground pests is secured by scattering dry salt underneath the cabbage plants.—S. L. B.

NOTES FROM 'FLORAIRE.

THERE formerly grew in gardens—at least, here in Geneva—a so-called Saxifraga japonica which I lost more than twenty-five years ago and only found again last year, in a very old garden near Montmorency in France. It is a form of sarmentosa, quite distinct of the type, and is not the S. japonica, of de Boisseau, described in Engler's "Saxifragales," but a form of sarmentosa with thicker leaves, deep brown underneath, bearing longer and thicker hairs, and forming bushy tufts with a few very short stolons. The flowers are quite similar to those of sarmentosa and slightly spotted with pink.

Saxifraga florulenta has been called the gem of the Saxifragas. Indeed, it is one of the most elegant of all rock plants; but it is not of easy cultivation. It grows in a rather small area, between the Colle di Tenda to the Tinee Valley, always in dark clefts among the highest peaks, where it can send its roots very deep down between the narrow crevices of the rock. It is difficult to dig up, but I have found that the best way is to hunt for it at the base of the rock walls. There one may find sometimes large quantities of little seedlings that are very easy to take out and transplant. If you have a wall of granite, there the plant will certainly succeed. It is a lime-hater and cannot endure chalk. We planted a lot of these seedlings here in a turf wall; although the young plants were in very good health when brought home, they perished because of the presence of lime. But in pure peat we grow it easily, although it has not yet flowered. Perhaps our water contains too much chalk.

S. florulenta is a monocarpic plant which dies after flowering. However, the rosette of the plant is of great beauty, and it lives long years before flowering (much longer than longifolia, which is also monocarpic). I have counted the age of one plant in the Maritime Alps, and that was more than 100 years old. The flowers are of the sweetest carnation colour, lighter than those of retusa or oppositifolia. They form a regular pyramid, and flower from August to September. —HENRY CORREVON, *Floraire*.

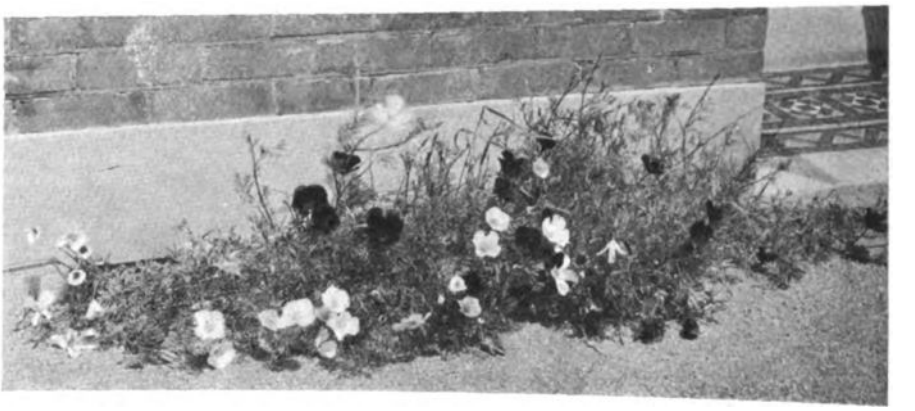
MAKING THE PATH BEAUTIFUL.

WHERE a path runs along close to the side of the house there is often no room for a flower bed. In the dry, stony situations there are few plants that will succeed, but an exception is to be found in the Californian poppy. Remove a little of the gravel here and there and then fill in pockets of soil. Sow mixed seeds of Eschscholtzia and over the seedling period water occasionally. Afterwards no attention is needed and the Californian poppies flower freely. Indeed, in the dry stony soil they often seem to do better than when growing in a well prepared border, especially if the situation is a sunny one. The plants hide the hard angle formed by the house and the path in a very satisfactory manner.—S. LEONARD BASTIN.



ESCHSCHOLTZIAS AS A PATH PLANT.

PRIMULA FASCICULATA.

THIS recently introduced species from China promises to be a precious and welcome addition to the already long list of primulas suitable for the rock garden and the alpine house. In this latter, it is quite easy to grow and flowers profusely (as will be seen from the accompanying illustration), though on the rock garden it needs a choice position, amply supplied with moisture during the growing period—yet sheltered from excessive moisture round the crown during winter. It forms a neat rosette of spoon-shaped leaves, about 1in. long and from ¼in. to ⅓in. wide, on a petiole 1in. to 1½ins. long. From this rosette of shiny, light green foliage rise in February or March, a number of slender stalks 2ins. high in the form of a fascicle (hence the specific name), each of which bears a single flower about ½in. in diameter. These flowers are of a bright, clear, rose pink colour with a small decided orange-yellow eye. The petals are deeply notched as in P. farinosa, though the depth of the notching as well as the depth of colour varies to some extent in the seedlings. If hand pollinated, with pollen from the thrum-eyed flowers dusted on the pistil of the pin-eyed ones with a camel hair brush, seed is set freely. This germinates easily if sown directly it is ripe, and the seedlings should be pricked out into well drained pans of light soil as soon as large enough to handle. These should be kept as hardy as possible and potted singly in a compost of good fibrous loam and leaf mould in equal parts with a little sharp sand added. Care should be exercised when watering so that the soil is not allowed to become soured by over-watering and also that no water is allowed to settle on the foliage, particularly during the winter months and while the seedlings are small.—R. B.

DEUTZIAS.

THERE seems to be an impression that the pretty Deutzia gracilis, which has for so long been grown in pots, is not perfectly hardy. This is quite a mistaken idea, for the plant will flourish out of doors almost anywhere, and when the conditions are suitable a dense bush about 2ft. high is quickly formed. To get the best results this plant must be growing in a very free soil and it will then produce flowers with the same abundance as it is to be observed in the pot examples. Providing the soil is thoroughly well drained, its actual composition does not seem to make much difference to this pretty little bush. D. crenata forms a much larger bush, which not uncommonly grows to the height of from 6ft. to 8ft. or even more. The foliage of this plant is large and rough and, when it is in flower, the slender shoots are adorned with masses of pure white blossoms. Two very distinct and extremely beautiful varieties of D. crenata are available. These are D. crenata flore pleno, with double flowers tinged with reddish purple and D. crenata candidissima, which bears quantities of double blooms of a snowy whiteness. This latter is probably one of the finest flowering shrubs available. All the deutzias are tolerant of a certain amount of shade and, if this is not too pronounced, they often do better than in a very open situation. Deutzias flower much more profusely if they are annually thinned. This is best carried out after flowering, at which time the old wood should be cut away and the new growth thinned. It is well to bear in mind that a very dense growth on the part of a deutzia tends to prevent a free production of flowers. Deutzias are easily propagated by the cuttings of short side shoots taken off with a heel of the old wood in the spring. These, if inserted in sandy soil, and either plunged in a propagating pit or covered with a bell-glass, root freely.—L. B.

PRIMULA FASCICULATA. A USEFUL SPECIES FOR THE ALPINE HOUSE.

THE MOUNTAIN CLEMATIS (C. MONTANA VAR. GRANDIFLORA).

ONE of the most beautiful climbing shrubs ever introduced to our country is the above, which is grown here (at Gravetye Manor), tumbling over a 9ft. wall which serves the purpose of a retaining wall to the flower garden. During May and June this robust, handsome shrub may be seen clothing the trunks of cedars and Corsican pine, garlanding their branches with snowy white flowers to a height of from 40ft. to 50ft., the great white wreaths of blossom even at this height being remarkably handsome and picturesque, while the columns of the trees themselves are draped with bloom and are of noble appearance. This robust shrub is really too large for walls of medium height, although it may be used effectively in such positions for a few years. The ideal site, nevertheless, is a large holly or other evergreen tree, where its long flowery trails are free to rise or fall and are safe from the pruner's attention.

Such trees provide a charming background for its snow white mantle of bloom, and the companionship looks very natural.

The small gardener who does not possess such trees has no cause for despair, as, with a few rough poles to form a tripod, he is able to cultivate and enjoy the flowers of this indispensable climber from the Himalayas.

In a famous garden near me this clematis has been used to form a large screen to obscure some buildings in the rear. The screen rises many feet above a large brick wall, and few things are more striking than this glorious mass of bloom each year.—E. MARKHAM.

[SOLDANELLA ALPINA.

IT was during August many years ago that I first saw this beautiful little plant growing high up in the Alps near Davos at a little place called Sertig Dörfli. It was flowering at the edge of a snowdrift, and gave me quite a thrill, for I had read

Digitized by Google

what Ruskin had to say of it in his "Frondes Agrestis," where he is speaking of the beauty of snowdrifts. He describes it well and accurately with his usual exuberant flow of language: "Through these"—openings in the snow—"emergent a slender, pensive, fragile flower, whose small, dark purple-fringed bell hangs down and shudders over the icy cleft that it has cloven, as if partly wondering at its own recent grave, and partly dying of very fatigue after its hard-won victory."

This diminutive little plant, rising only a few inches above its dark green leathery leaves, is a treasure for the rock garden or the alpine house. Coming as it does from the regions of eternal snow, it must be carefully placed on the rock garden so that its roots can never get dry in summer, and it is as well to afford it some protection in winter, not from cold but from excessive moisture from above. Reginald Malby, in "The Story of My Rock Garden," describes how he constructed small bog gardens by forming little cups in the ground with beaten clay which he filled with good peaty soil and leaf-mould. In just such a position this soldanella will thrive. It must be given some choice little corner where more vigorous plants cannot encroach upon it, and it must not be forgotten that it shows a preference for partial shade.

In the alpine pastures it is found at from 5,000ft. to 9,000ft., and often comes into flower in hollows under the snow where the temperature at most cannot be more than a degree or two above freezing. If we remember that its two great enemies are wet in winter and drought in summer, there is no reason why we should not be successful in growing this little foreign relative of our homely primrose.—EDWARD CAHEN.

THE SCARLET CLUSTERS OF MALE FLOWERS OF ACER RUBRUM.

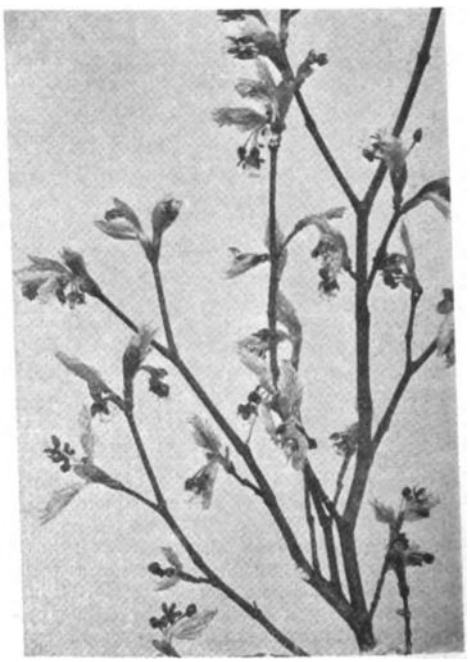
FLOWERING MAPLES.

AMONG our spring-flowering trees and shrubs there are so many species with very showy attractive flowers that we often neglect others of which the flowers seem at first sight to be rather inconspicuous. Especially is this the case when the different kinds of maples burst into bloom. I wish in this note to call attention to some early-flowering species that are frequently met with in collections.

The best known of them is, probably, Acer rubrum, the red maple, a stately North American tree, one of the most beautiful of its family in the New World. How I admired the giant trees in the Arnold Arboretum when, in March or April, the twigs were literally covered with the scarlet clusters of the male flowers. At this early time of the year the red maple is hardly less attractive than in the fall, when its foliage turns red, scarlet and yellow. A few days later the pistillate flowers which are either on the same or, more often, on different trees, develop and are quite different. In its native home the red maple attains a height of about 130ft. It has been well known in Great Britain and on the Continent for nearly three hundred years, and I know of specimens hardly less magnificent than those in the eastern United States.

The male flowers of another well known North American maple are also attractive. This is the western form of the box elder or ash-leaved maple, Acer Negundo var. californicum, sometimes regarded as a species. It differs chiefly from the type by the densely hairy branchlets, leaves and fruits. A. Negundo is easily distinguished from other maples by its pinnate leaves, and also by its dicœcious flowers, the male and the female being borne on different trees. The box elder came to Europe at about the same time as the red maple.

A very ornamental maple, too, when in full bloom is the vine maple, A. circinatum, which was brought to Europe by Douglas from the north-western United States exactly a hundred years ago. It belongs to the same group as the Japanese maple, and is mostly shrubby in habit. Britton says that the common name "vine maple" refers to the trailing or half-climbing habit of the tree, but I have never seen large specimens showing this interesting character. In April, when the flowers appear, together with the silky young leaves, the purplish sepals form a striking contrast with the whitish petals and the showy crimson-hued bud scales. The twigs also are rather a shining purple. This handsome American maple is of the greatest ornamental value, and is growing well in places where its Japanese cousins often do not succeed. Its spring beauty is almost surpassed by the conspicuous red and orange colours of the leaves in the autumn. It is an excellent species for smaller gardens.—CAMILLO SCHNEIDER.



TWIGS OF A. CIRCINATUM IN SPRING.

DELPHINIUMS FOR THE BORDER

BY EDWIN BECKETT.

PLANT fashions, like those of dress, are ever-changing, and one floriferous beauty that has been gradually coming into her own is the subject of these few notes. I confess to have been greatly attracted to these perennial larkspurs, and during the past few years have raised not a few new seedlings and, in addition, tried out many of the novelties raised by our leading specialists. Many of these however, are out of reach of the owner of the suburban garden, and the purpose of these notes is to help him in a selection of really good novelties that may be obtained in commerce at reasonable prices. They are all good garden varieties and a few will give every satisfaction in the garden.

THE ALAKE.—One of the first varieties which an amateur should go for. Fine spikes of large purplish blue dark flowers, so pretty in their arrangement.

CAPRI.—This, sky blue, in fine contrast to the foregoing, is an ideal cutting variety for vases, of good, loose-growing habit.

FANNY STORMOUTH.—Small of spike, but free in growth, this is excellent for cutting for decoration or for bedding work, and is of a pretty clear medium blue.

GENERAL SIR DOUGLAS HAIG.—A beautiful variety of strong character and excellent spikes. The colour is best described as purple mottled with blue, and is most distinct.

HARRY SMETHAM.—One of the older varieties, and still one of the most attractive, with its "porcelain blue" flowers, semi-double, and robust habit.

COSSACK.—More modern and a fine clear bright blue with a "bronzy eye," like a bumble bee; very distinct and good.

EDWIN BECKETT.—Again not modern, but a very strong grower, going up to 7ft. at times, with well placed purplish blue flowers. Good spikes and a good doer.

IDA R. ELLIOTT.—Large spikes and flowers of light-toned bright blue.

JOAN CARTER.—Mauve-toned flowers, good habit, semi-double, fine for cutting.

KING OF THE DELPHINIUMS.—The true variety is first class, tall growing, massive spikes of large (2in. diameter) gentian-coloured flowers with white eye. There are many inferior stocks of this variety.

Digitized by Google

LA FRANCE.—An appealing variety with pink tones running through the lilac semi-double flowers. Very fine spikes.

LAVANDA.—As its name denotes, lavender shade of flower; semi-double, borne in long, thickly clad spikes.

LE DANUBE.—A pretty variety of pale blue, with a pinkish centre.

LORD DERBY.—Very distinct in appearance. Large flowers of deep blue and rosy mauve tones.

LOVELY.—This variety is well named. Fine spikes, flowers lavender-toned bright blue with white eye.

MILLICENT BLACKMORE.—This I look on as one of the best. Spikes gay pyramids of pale mauve-toned blue, very large flowers.

MOERHEIMI.—Worth growing as being a 6ft. tall white-flowered variety of merit; good for cutting and garden effect.

MRS. A. J. WATSON.—Another of the "mauvey" blues, and very free-flowering, and of tall habit and vigorous growth.

MRS. CHRISTIE MILLER.—As a contrast to the blues this cream-coloured variety is well worthy of inclusion, being one of the best with well formed spikes.

MRS. COLIN MCIVER.—A pretty semi-double of heliotrope shade.

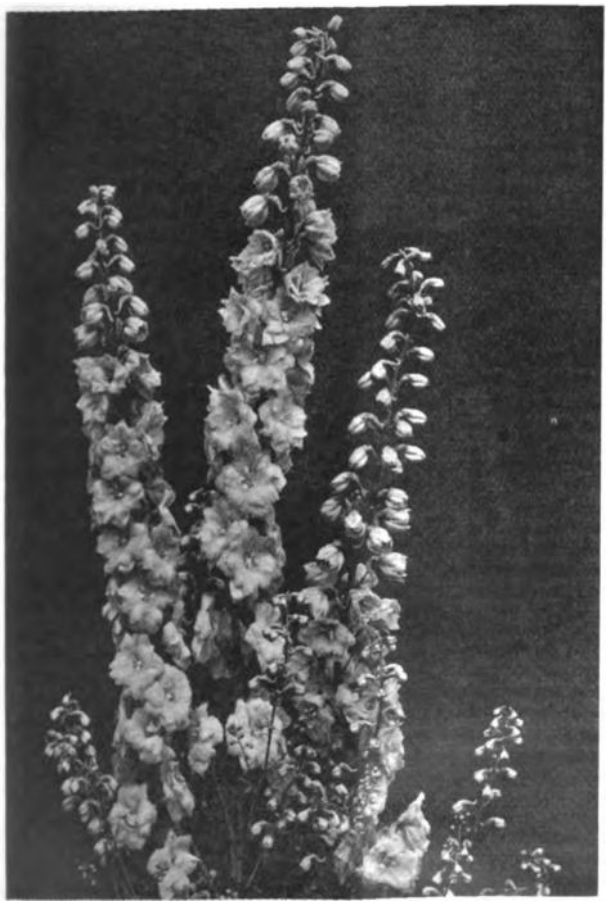
MRS. H. KAYE.—This has a distinct feathery appearance and is a good dark blue shaded with purple.

NORAH FERGUSON.—One of the most distinct varieties, and a general favourite with all growers. It has very fine spikes of pink shaded, pale blue flowers, semi-double in character and with good white eyes.

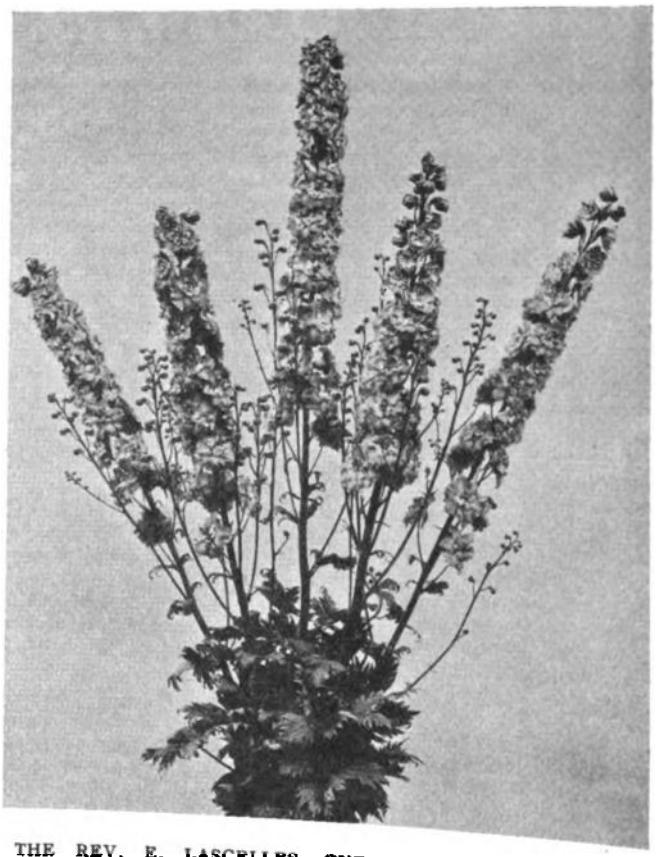
PERSIMMON.—The large circular flowers of medium blue, the strong, branching stems and good general habit make this one of the best for all classes of work.

QUEEN MARY.—The colour of this is generally classed as "silver blue." It is a handsome thing with good semi-double flowers.

REV. E. LASCELLES.—One of the older varieties, and still one of the very best, with large, fine spikes, the flowers of which are intensely blue, contrasting well with the white centre.



NORAH FERGUSON, MOST DISTINCT AND A GENERAL FAVOURITE.



THE REV. E. LASCELLES, ONE OF THE BEST OF THE OLDER VARIETIES.

STATUAIRE RUDE.—A really charming variety of heliotrope shade.

One could go on listing the many fine things, but I think the above selection contains the "pick of the bunch," other than one or two of the belladonna varieties, which must not be overlooked. These are excellent for growing well massed together, being of more dwarf stature than the general run of delphiniums and of slighter build. Flowering over a very long period, they are especially valuable as cut flowers.

Of this class my selection would be Capri, a pretty sky blue; grandiflora, of similar shade, but suffused with a mauve tint; Lamartine, a violet tone of azure blue with a white eye; Semi-plena, really an improved Belladonna of semi-double flowers clear blue in tone; and Theodora, a fine loose-growing variety with medium blue flowers.

The soil wherein the plants are grown should be good, neither light, poor—which tends to starve them—nor tenacious, wet clayey soil, which handicaps them, if, indeed, it does not kill them from the start. Other than this, the delphinium is not fastidious. To get the soil into good condition, work it deeply and add plenty of lime, wood ashes, leaf-soil and such material.

Place the plants in their growing positions in March or early April, and surround each one with a ring of sharp cinder ash to keep away slugs, which have a great partiality for delphiniums. Do not let the cinder ash *touch* the stem. Support the plant as it grows with stout stakes, but do not let them be too obtrusive, for, the habit of the plant being somewhat open, stakes that are too apparent will detract from the beauty of the subject. Space permitting, allow the plants to grow a yard apart each way, and give a sunny position for the best results. Increase of stock can be effected by careful division in spring, by cuttings at the same period of young shoots taken off with a portion of the root stock attached, which may be struck in a cold frame, or by raising from seed, which can be done in the open ground, sowing as soon as the seed is ripe. Raising plants from seed forms a pleasant hobby and in addition plenty of material is obtained for cutting, and there is always the possibility of coming across a really improved new plant.

CORRESPONDENCE

SPRING FLOWERING ROCK PLANTS.

SIR,—Is it worth recording that one plant of Primula Allionii is in flower in my rock garden to-day (February 28th) and another shows clearly a pink bud?

A plant of Androsace carnea Laggeri is also dotted with pink buds and will, I fear, be over before I see it again.

If you care for it, here is a complete list: Anemones fulgens, blanda, Hepatica, Hepatica rubra and angulosa; Iris reticulata and I. persica; Narcissus minimus, N. triandrus and N. cyclamineus; Crocus versicolor and C. Tomasinianus; Saxifragas apiculata, a. alba, Elizabethæ, Faldonside, Haagii, Rochelliana, Grisebachii, Biasolettii, Irvingii, Burseriana crenata (B. gloria and sulphurea are over, and so is Kellereri), Blickii, macedonica, Mrs. Leng, scardica, Paulinæ, Salomonii, sancta, lævis, pungens, Petraschi, Myra and oppositifolia; Daphne Blagayana; Muscari azureum; Tulipas Kaufmanniana, polychroma and Turkestanica; Primulas marginata, Winteri, The General, Dusty Miller, denticulata, d. alba and Robertson Hall. One plant of Omphalodes Luciliæ shows the blue of its buds.—AUSTEN CHAMBERLAIN, *Five Ashes, Sussex.*

TWO EARLY FLOWERING SHRUBS.

SIR,—Those interested in early-flowering shrubs might include, besides those enumerated in the issue of THE GARDEN, January 2nd, page 2, the earliest flowering witch hazel, Hamamelis vernalis. While not so attractive as H. mollis, it was certainly cheerful to find it covered with its small yellow flowers on New Year's Day at the Arnold Arboretum. The flowers continue over a longer period than is the case with its more popular cousin. The narrow petals are about half an inch long, usually yellow, but on some bushes may bear a reddish tinge. The calyx is red but varies in shade with different individuals, as also does the fragrance, on some bushes being decidedly sweet, while on others no suspicion of scent can be detected. The time of flowering varies according to the intensity of the cold here—that is, from the end of December to March—and the flower buds will stand considerably more than those of H. mollis; but a severe winter—such as we experienced during 1917–18, when the glass did not register above zero (Fahr.) for a week and the ground, lacking the protection of snow, froze solid for a depth of over 5ft.—did kill them. It grows here about 8ft. high and almost as much through, owing to its peculiar habit of throwing up numerous suckers, forming quite a thicket, and which afford a ready means of propagation. It also comes readily from seed, and, contrary to the prevalent idea that these may take two years to germinate, if sown in December will be above ground the following May and fine stocky young plants are in evidence by the next fall. It must be remembered in passing that, like the seeds of Fothergilla, the fruits must be gathered and placed in paper bags in a warm house before they open, otherwise, if allowed to ripen on the bush when the capsule opens they fly far and wide.

Grafting done on H. virginiana in March will produce fine healthy plants by September, but look out for suckers from the stock and avoid this method of propagation if possible. Perhaps, in passing, attention could be called to another early-flowering shrub which appears to be little known, namely, Corylopsis Gotoana, and, while not strictly a January or February shrub, it flowers before the leaves unfold, which in this locality is early in May. Forming a stately shrub, it reaches the height of 6ft. with an equal or greater diameter, clothed with branches to the ground, and is, therefore, an elegant subject for lawn decoration. The conspicuous flower spikes are pendulous, pale yellow in colour and of a pleasant fragrance. The flower buds will stand a lower temperature than any other corylopsis growing here, and came through uninjured the winter recalled above, whereas during almost every ordinary winter here the flower buds on the other species are killed to a great extent. It comes from elevated regions in central Japan, and has been growing in the Arnold Arboretum over twenty years, and, while it has never produced any seed, may be increased fairly readily from hard or soft wood cuttings inserted in a frame with bottom heat.—WM. H. JUDD, *Arnold Arboretum*

IMPROVED SWEET PEAS.

SIR,—In connection with the interesting article on "Sweet Peas of Yesterday," I send you the enclosed note, as it refers to a matter I have never seen in any book on the subject. There have been several publications devoted to the sweet pea, but none of them so far as I have read contains information of the why and wherefore of the late Mr. Henry Eckford's beginnings, any way as I know it. I first came in contact with him when gardener to Dr. Sankey at Boreatton Park. This was in the 'seventies. It is admitted that no man has done so much in the way of improving this popular flower, and who succeeded in producing new types of exceptional beauty and novel colours. Being of an enterprising nature, he saw possibilities. He asked us (I was at the time associated with Messrs. James Carter and Co.) to supply him with a collection of seeds of distinct varieties, and we sent him Invincible Scarlet, for which we had received a certificate from the Royal Horticultural Society in 1865. Violet Queen (see particulars below); Butterfly, raised by Messrs. Sutton and Sons and figured in colour in THE GARDEN, January 12th, 1878; Prince of Prussia, The Queen and Giant Purple. Among his earliest improvements I am enabled to name the following with parentage: Black Prince (Giant Purple × Invincible Scarlet); Victoria, rose dashed with pink, white wings with edge of blue (Violet Queen × Prince of Prussia); Lottie Eckford, nearly white, if I remember rightly, with black seeds (Violet Queen × Prince of Prussia); Duchess of Albany, pink, black wings (Violet Queen × Prince of Prussia); Leviathan, rosy red and white (Scarlet Invincible × The Queen); Grandeur, scarlet rosy purple wings (Scarlet Invincible × The Queen); Blue King and Indigo (The Queen × Prince of Prussia); Salmon Queen (Captain Clarke × Butterfly). I should mention that Violet Queen was raised by Messrs. Carter and Co. and illustrated in colour in their seed catalogue for 1878 with this remarkable description:

"A new and distinct Sweet Pea Violet Queen, see Coloured Illustration. It is now several years since any novel form of this popular flower has been introduced, and the charming variety offered above will, we feel sure, be universally welcomed. Violet Queen sweet pea originated at our seed farms, and while we are enabled to give it most unqualified recommendation, we cannot, we feel sure, speak in too great praise of its beauty and novel character. It is dwarfer in habit than the other varieties, and the seed is also quite distinct in appearance [It was more square than round.—D. McD.], the flowers ranging in colour from deep mauve petals to light violet at the keels, suggestive of the beautiful bougainvillea. Our manager at the St. Osyth Seed Farm considers this pea to be entitled a sub-species, and for the uses of botanical registration we purpose identifying it as Lathyrus odoratus heterosperma, and we look forward with much interest to other introductions from this parentage which appears likely to be the forerunner of quite a new form of this favourite summer flower."

The following paragraph appeared in THE GARDEN, July 27th, 1878. It is signed by a gardener who had to be reckoned with in his day:

"VIOLET QUEEN SWEET PEA.—This remarkably distinct and valuable variety is dwarfer in habit than any of the other varieties which I have grown. Indeed, the seed itself is so different from that of other kinds as to suggest the idea of its being a distinct species, which is not, however, the case. The colour of the flowers is such as to be, as has been stated, suggestive of the beautiful bougainvilleas; consequently, they are exceedingly useful for the purpose of cutting for bouquets or for furnishing vases, as they are equally highly perfumed as the other varieties, while the plant itself, whether grown in lines or in patches, is exceedingly ornamental, its dwarf habit of growth being greatly in its favour.—P. GRIEVE, Culford."

The fact that Mr. Eckford did not receive certificates for any of his novelties until early in the 'eighties is convincing evidence that he worked upon the list shown above, which from my view provides the names of the original parents of the modern sweet pea.—DONALD MCDONALD.

THE POPULARITY OF THE PEONY.

SIR,—We have just received a letter from Mr. A. M. Brand from Minnesota, U.S.A., and as Mr. Brand is president of the American Peony Society—a body of considerable importance—and as the letter puts into words my own thoughts and desires, you may care to publish it in the hope that eventually the peony may become really popular in this country.—JAMES KELWAY.

"GENTLEMEN,—I have understood, as you state in your letter what seems to many of us in this country to be a very strange thing indeed, that the peony is not so popular in Great Britain as it is with us and with our Canadian friends across the lines. From what I have heard of the English climate, it must be ideal for the bringing out of peonies to their very best. In the northern two-thirds of the United States and in the southern half of Canada wherever flowers can be grown there is no flower that compares to the hold the peony has with the people. It is the flower pre-eminent. We grow beautiful roses, we grow all the flowers of the north temperate zone, but no flower is so much thought of and sought after as the peony. This has been true only since the introduction of the choicer peonies, such as have been coming out during the last twenty-five years. Your firm has been very fortunate in the high standing of the comparatively large number which they have added to this list. No peony collection with us is considered complete until it numbers among its varieties Kelway's Glorious, James Kelway, Baroness Schroeder, Phyllis Kelway and Lady Alex. Duff.

"The appreciation of the peony has been brought about through the untiring efforts of the American Peony Society, which is a society international in scope, through many local peony societies, many of which are of considerable size, through the many excellent peony shows which these societies stage during the peony season and also through the heavy advertising campaigns carried on by the large peony growers during the selling season.

"I am glad to believe from what I have read and heard of the English soil and climate that your results with the peony would be more uniformly good than our results. We have too much hot, dry, windy weather apt to visit us right during the blooming season."

KNAP HILL NURSERY
WOKING, SURREY
(late ANTHONY WATERER)

PROPRIETOR - **HOSEA WATERER**

has pleasure in offering

STANDARD TREES

in great variety, consisting of

LIMES, NORWAY MAPLES, ELMS, etc., etc.

EVERGREEN & DECIDUOUS SHRUBS, viz. :

Box—Green and Variegated, 3 to 8 ft.
Hollies—Common, 5 to 8 ft.; Variegated and Green varieties, 2 to 6 ft.
Thuiopsis borealis, 10 to 12 ft. Cupressus Lawsoniana, 12 to 14 ft. Cedrus atlantica glauca, very fine, 14 to 16 ft. Osmanthus, Phillyroeas, Spiræas, Lilacs, Viburnums, etc.

GOLDEN YEWS

A Magnificent Stock in all shapes and sizes from 2 to 10 ft.

PRIVET, Common and Oval-leaved.
QUICK and **HORNBEAM** for Hedges.
AZALEAS, 2 to 5 ft.
RHODODENDRONS, without doubt the finest stock in the trade of named varieties, 2 to 6 and 8 ft.
HARDY HEATHS in great variety and a good general nursery stock.

Catalogues ready.

Enquiries and inspection invited.

THE GARDENS AT OLYMPIA

YEAR by year, the standard of the gardens at the Ideal Home Exhibition has shown decided improvement, and in this year more than ever the various nurserymen who are exhibiting have excelled all their previous efforts in the laying out of the gardens. It may be that an indoor position lends itself to more skilled treatment, since the weather conditions have not to be contended with. On the whole, however, although the actual design and lay-out would be hard to better, the gardens look a trifle "shoppy." They resemble in many cases a tightly packed and crowded shop window. In a way, such a method of exhibiting is excusable when the exhibitor has much to show; but, on the other hand, it is a bad habit to cultivate. The onlooker gains an altogether false impression of what a well proportioned garden should really look like. The plants themselves lose that individuality which is one of their chief charms, and, moreover, from the point of view of culture, they cannot and will not grow so close together as shown. Still, these are minor details which may, perchance, only strike the practised eye; but the general effect of the gardens as a whole is both pleasant and charming. The majority of garden plants are represented in shrubs, alpines and bulbous subjects. The predominant tone of colour is provided by the at once vivid and delicate hues of the azaleas; while a more sombre note is introduced to the scheme by the use of evergreens in many forms.

Probably the most ambitious and certainly the most effective garden is that laid out by Messrs. Carters of Raynes Park. It represents a stream glade such as may be found on a day's trek through the Lake District. A tumbling and rushing stream forms the central theme on the sloping grassy bank. From the background of tall conifers which lend that natural touch of enchantment to the scene, one finds drifts of primulas nestling at the edge of tiny pools flanked by a few plants of Prunus triloba. A clump of bamboos looks well as a sentry to the main pool on the lower level, which is most attractive with its groups of yellow and white trumpet daffodils and narcissi. Patches of Erica carnea here and there give to the whole design just that touch of reality which is so necessary to render the lay-out natural and attractive. Messrs. Carter are also responsible for the effective design of the Dutch Tea Garden.

The Anemone Garden, arranged by Messrs. Reamsbottom, is a novel feature among the exhibits. Here there are beds planted up with the gaily coloured St. Brigid anemones for which this firm is famed. The clumps, laid out in mass for the sake of colour effects, are most striking, those around the fountain in the centre of the little formal garden being particularly so. The dark background of evergreen shrubs considerably enhances the appearance of these excellent hardy border flowers, which should be far more grown in gardens both large and small. This exhibit, so tastefully displayed, should do much to popularise the flower.

Not a few gardens are laid out as rockeries or stretches representing an alpine meadow. Messrs. The Central Garden Supplies, Limited, make full use of weather-worn limestone in their rock and water garden. Flowering shrubs, notably azaleas, with heaths and bulbs, all combine to form a pleasant picture. A small rockery planted up by this firm contains a few dainty alpines, but the general appearance is too stiff and set. More latitude might have been allowed to convey the idea of natural and broad masses of bloom. Mr. G. G. Whitelegg's rock garden is most attractive. The individual plants nestling in crannies here and there, especially the saxifrages, are well grown and contribute much to the charm of the garden. A pleasant idea of spaciousness is obtained in the lay-out of this garden, as is also the case with that designed by the Orpington Nurseries after the style of a broad expanse of alpine meadow with a rocky escarpment as a background. Many fine azaleas are also staged by Mr. Whitelegg, of which the most striking is the brilliantly warm-coloured Van Thol, which appears at its best with a background of sombre cypresses.

A small and irregular little garden, aptly termed "The Back o' Beyond," is displayed by Messrs. R. Wallace. It illustrates how an amateur can make full use of even a tiny piece of ground. A garden shelter built of chestnut and a pleasant little dove cote with thatched roof combine happily with the surroundings to provide a harmonious garden scheme. The association of the white-stemmed birches with drifts of Erica carnea, interspersed with clumps of nodding daffodils, is wholly springtime-like in its effect.

The semi-formal garden constructed by Messrs. Cheals is interesting, and also illustrative of yet another way of furnishing small spaces. A lily pool forms the central feature, while beds of hyacinths contribute colour and fragrance. The outside borders contain many shrubby subjects of interest, such as azaleas and hybrid rhododendrons, of which Cynthia, with its upstanding trusses of crimson flowers, is most striking. Examples of topiary work are also to be seen.

The dainty little violet is given a garden all to itself. It is well arranged by Mr. Baldwin Pinney, whose fame as a violet specialist is as well known as the charms of the fragrant little flower. Another solo garden is the Carnation Terrace Garden, designed by Messrs. Allwoods, in which they show their perpetual-flowering and hardy border carnations to distinct advantage. Messrs. L. R. Russell of Richmond provide a gorgeous array of early-flowering shrubs in which the light blue of Wistaria sinensis stands out conspicuously. Many of the azaleas, such as Himodigeri and Hinomayo, which this firm can do so well, are tastefully shown.

A formal garden of somewhat uncommon design is arranged by Mr. Reginald Winder. Herein is housed a collection of roses, polyanthas and ramblers, worked out in a colour scheme of pink and white. The hedge enclosing the garden is formed of that excellent new hedge shrub, Lonicera nitida.

One of the most striking gardens is the large circular formal one constructed by Messrs. Luff and Sons. Four imposing entrances lead to a central figure and fountain. The pergolas at the entrances are draped with Wistaria sinensis, while the raised beds are filled by upstanding fragrant hyacinths in all colours, flowering cherries and magnolias. It is a comprehensive collection of early spring subjects and is well worthy of the attention of all enthusiastic gardeners.

To complete the list there is the rock garden designed by Mr. Crewdson Day, which chiefly consists of a grassy slope with a scree or moraine garden in which are placed a few primulas. A semi-formal garden in which beds of blue hyacinths are laid out is especially attractive.

These gardens will be found exceedingly helpful to the everyday gardener, in that they contain numerous suggestions in their make-up which will both assist and stimulate him to further effort.

AQUILEGIA TRIALS AT WISLEY

THE Royal Horticultural Society will carry out a trial of aquilegias in their gardens at Wisley during the next two seasons. A packet of seed of each variety to be tried should reach The Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before March 27th, 1926. The necessary entry forms may be had on application to him.

PRIMULAS

THROUGH our slip an unfortunate error crept into Dr. Macwatt's article on Primulas on page 134. Primula La Lorraine should have been mentioned as a hybrid between P. Sieboldii and P. Veitchii. P. kewensis is, of course, a hybrid between P. verticillata and P. floribunda and comes in the floribunda section.

TRADE NOTES.

IT is beneath the surface that slugs, beetles, wireworms and leather-jackets work their mischief, and it is beneath the surface that Kilogrub combats them.

Dug into the soil before planting or dibbled around the roots of growing plants, the penetrating and powerful fumes of Kilogrub make short work of soil pests, but it is quite harmless to plant life.

Kilogrub is made by Messrs. John Peak and Co., Limited, Wigan, and is obtainable from all seedsmen.

THE possession of a perfect lawn is the ambition of all interested in tennis or croquet, for without it accurate play is rendered impossible. How difficult of attainment this is by ordinary methods all lawn lovers know. In Velvas Lawn Sand, however, they can find the perfect remedy. This product of Messrs. Robinson Brothers, Limited, West Bromwich, not only destroys every kind of noxious weed, but actually feeds the grass; it encourages the growth of finer grasses—which ultimately form well knit turf.

We can confidently recommend it for all lawn troubles, and advise those who do not know its virtues to give it a trial.

IMPORTANT ANNOUNCEMENT

by SAMUEL RYDER.

OWING to the altogether phenomenal demand for the Ryder 1926 Catalogue I appeal to customers and others who have copies in their possession to make the utmost possible use of them. A reprint edition (necessarily limited) is in the hands of the printers, but those who have copies will greatly assist us by lending them to their friends and neighbours as soon as they have finished with them.

By sending orders at once you will ensure prompt receipt of your full selection of seeds without disappointment, but you should make out and post your order at once as the season is advancing and sowing time is here.

Friends making use of your Catalogue may write their order on a separate sheet of paper, but please ask them to write it in Catalogue numerical rotation, as this greatly facilitates the prompt dispatch of orders.

RYDERS QUALITY SEEDS IN 2d. PACKETS for Flower and Vegetable garden.

RYDER & SON (1920), LTD.

GARDEN TECHNIQUE

THE FLOWER GARDEN

VIOLETS.

THE plants have done remarkably well this year, so far, the individual flowers being very fine, on well cultivated plants. It is good cultivation that results in such satisfactory conditions, and those who are disappointed at the present time should note the cause of failure. Good cultivation means careful attention to the plants the whole year through. The right time to begin is the present, whereas it is during the spring months that thousands of plants are neglected. Plants growing in frames should be closely examined and all useless runners cut off. Stir the soil between the old plants with a pointed stick, and remove any old discoloured basal leaves, as it is on such that red spider finds a home early in the spring. The number of young plants required for frame work next winter, and the number for open border cultivation, should be ascertained. In the meantime, the summer quarters for the young stock should be prepared. It should be remembered that violet plants growing steadily and strongly in a moderately rich soil will be, as a rule, free from red spider. A sandy soil should be heavily manured with rotted manure; a hard, clayey soil must be lightened somewhat by the addition of rotted leaf-soil, old potting soil and burned refuse from the garden smother. In a soil of this kind grand plants will be available by next September. Without the lightening material the plants will be failures. I once saw some puny young plants in a hard, clayey soil in the month of July: at this date they should be well established. A border on the north or north-east side of a wall or fence is an ideal one.—G. G.

PLANTING SWEET PEAS.

THOSE who have sown sweet pea seeds in autumn—say throughout the first or second week in October—and wintered the plants in cool conditions should now

SALE OF ROSES

At 33⅓ per cent. less than catalogue prices.

HAVING so far sold our stock of Roses that the catalogue is no longer a reliable source of selection and not having enough each of different kinds to justify advertising the balance in named collections, we are offering what remains of our stock of bush, standard and climbing Roses in carriage paid quantities in varieties of our selection, at 33⅓ % less than list prices.

The varieties are all first-class (not an obsolete one among them), the trees are excellent and, while all buyers will get remarkably good value for money, the first comers will have the advantage of newer and more expensive varieties for as long as stocks last.

have sturdy, clean and well rooted plants 6ins. or more high. These plants should not be allowed to get overcrowded and spoiled, so each one should have his plants set out within the next week or two.

Some growers will have their plants in pots, while others will have them in long—6ft.—narrow wooden V-shaped boxes. Plants as a rule do quite well grown in either pots or boxes, so long as the cultivator understands how to care for them.

When the surface soil is dry and in workable condition, the plants should be planted in the open border where they are to bloom. A sheltered and warm situation is the best place to choose at this early season, with the rows made to run north and south. The surface soil should be lightly forked over and made level, and if rough it should be raked. The line should then be stretched and a groove about 6ins. deep taken out with the spade.

The ends should then be removed from the boxes and with the help of an assistant each box can be lifted and the contents slipped into the groove without very much disturbance to the plants. By this method the plants receive little or no check, but, instead, they make good headway when once established, and as a rule far surpass in vigour and floriferousness pot-grown plants, which have to be separated at planting-time.

As soon as planting is completed, dust lime along each side of the plants. This is beneficial to the soil and will also deter slugs from getting to the young stems. Little twiggy sticks should then be set at each side of the rows to keep up the stems and act as a shelter screen. This is all the plants will require for some time.—D. ARMSTRONG.

VEGETABLES

RHUBARB.

FEW gardeners seem to realise the value of rhubarb, and hundreds of people who are particularly careful about what sort of potato or onion they grow, do not give a moment's thought to the selection of a good variety of this useful vegetable.

Now, there are rhubarbs and rhubarbs. Some are early and others late: some are green and others red; and some are small and others large. Champagne is a very good early sort, and one which forces well. Victoria is another good one, though rather later. Daw's Champion is one of the biggest sorts, and Sutton is an excellent kind to plant for bottling purposes; it keeps its colour splendidly.

March and April are the best months to make new plantations, and the ground should be deeply trenched and well manured. Propagation is usually effected by division of the old roots, outside buds with vigorous young roots attached being chosen. The ground should be forked over and made fine and level, and the roots set, with the buds 2ins. below the ground level, 3ft. apart in the row, and the same distance from row to row, except in the case of the large-leaved sorts, which require rather more space. Make the soil firm about the roots, and then obliterate the footmarks with a fork to leave a neat finish. If some good decayed manure can be obtained, give the old buds a dressing and fork it in. The life of rhubarb beds depends largely on the amount of manure they receive from time to time, and well looked after they will last from five to ten years.

Pull a little when up, then leave the stalks to grow sturdy. If the stalks are pulled with discretion, the crop will last right on until the autumn. When once planted rhubarb needs little attention; it likes water, and the roots do with a change every few years,

Austins
Scotch Seed Potatoes.

LOWE & GIBSON
CRAWLEY DOWN, SUSSEX

though splendid crops often come up year after year from roots that are never moved. —R. D.

PLANTING.

A STUB, or dibber, is not so suitable for planting flowers or vegetables as a trowel or a small spade. When a dibber is used, the roots of the plants are liable to be crumpled or bunched.

Plants are best transplanted with a ball of soil adhering to their roots. Without breaking up this ball too much, care should be taken in planting to spread out the rootlets. This cannot be done if the plant is simply popped into a hole made with a stub, or dibber.

It is also important to firm the roots well, so that there will be no check to growth. Potatoes, when sprouted, are sometimes planted with a dibber; but it is a better plan to open a shallow trench with a small garden plough, or a well worn spade, and to plant the sets therein. Then draw a little soil over the tubers with a hoe or a rake.

In planting cabbages, strawberries, etc., which require a fairly firm roothold, it is best to roll or tread the plot to beg n with, and rake the surface level. Then line off the rows and cut out a shallow trench, or "sheugh," for the plants. Space the plants at the required distance apart. Plant to the proper depth, and cover the roots with the soil. Tread it firm around the plants.

The largest leaves of cabbages, etc., may be cut off before planting. When this is done the plants take root much faster, especially if the weather is somewhat dry. The reason is that the plant gives away less moisture when deprived of its more expansive outside leaves,

One good watering is better than repeated sprinklings. If the hoe is used frequently among growing crops, little watering, as a rule, will be needed.—J. W.

BRUSSEL SPROUTS

I HAVE just completed a variety trial of Brussels sprouts. The results have such a definite practical value that I should like to pass them on to others while they are fresh in my mind. The crop was grown in firm, moderately rich soil and in an open situation. Each variety was tested for firmness of sprout and ability to button near the ground. The varieties tried were The Favourite, Harrison's X X X, Dalkeith, Wroxton, The Darlington, Ormskirk Giant and Aigburth. First place must be given to the variety The Favourite. It forms sprouts as near to the ground as possible and every one is as firm as a rock. In addition the heads of the plants turn in and harden to cabbage form. Varietal characteristics are difficult to fix in the Brassica tribe, but the difficulties have been overcome in this case. Harrison's X X X is a thoroughly good sprout.

Dalkeith was rather disappointing. It emerged from the drought of summer in a forlorn condition, but recovered when rain fell. The lower leaves, however, turned yellow before sprouts could form and those which did form were not firm enough to be marked as good quality. I think Dalkeith is a variety which has had its day.

The Wroxton and The Darlington appear to be varieties of equal merit. Both develop good firm sprouts, but might amend their behaviour somewhat by developing them nearer the ground.

Ormskirk Giant is an excellent variety. It is tall in stature and a splendid drought-resister. The sprouts are large and solid and the varietal characters firmly fixed. If it had been possible to fix a stronger constitution in Ormskirk Giant, the variety would have compared well with the Favourite. The keen frost of the past winter left a definite mark upon it.—GEO. H. COPLEY.

I KNOW of a pipe tobacco which has for fifty years gained steadily in favour.

Generations have passed their verdict on its incomparable purity and excellence.

The greatest care is taken to ensure perfect uniformity of quality.

AUTUMN and WINTER BEAUTY

In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

WAKELEY'S Celebrated Hop Manure

(PATENTED)

THE ORIGINAL AND ONLY RELIABLE SUBSTITUTE FOR STABLE MANURE

DIPLOMA AND MEDAL, ROYAL INTERNATIONAL HORTICULTURAL EXHIBITION, 1912

DO YOU REALISE IT?

A large bag of WAKELEY'S PATENTED HOP MANURE at a cost of only 7/- carriage paid to your door (if within 25 miles radius of London, or at a trifling extra if beyond), GOES AS FAR AS A CART-LOAD OF STABLE MANURE, without any of the defects of the latter; gives better results, is easy and clean to use.

Every ounce of Wakeley's Hop Manure is of value to the soil, supplying the necessary HUMUS in addition to the valuable plant food. Worthless rubbish is not added to make weight (as is the case of some artificial manures advertised).

Thousands do realise it, the proof of this is the constant flow of UNSOLICITED LETTERS received from time to time in praise of the wonderful results obtained at such a moderate cost (see Booklet for selection).

BEWARE OF IMITATIONS.—Genuine Only in our Marked Bags containing Guaranteed Analysis.

ILLUSTRATED CATALOGUE giving full particulars and testimonials sent on receipt of post card.

CASH PRICES (including bags):

Small (about 1 bushel)	3/-
Large (about 4 bushels)	7/-
5 Large	33/9
10 Large	65/-
20 Large	120/-

Carriage paid by Pickford's or to any station within 25 miles of London, including delivery if within free delivery radius of Railway Company; 6d. per bag extra for every 50 miles or part beyond. Maximum extra charge Great Britain, 2/6 per bag.

TUBS FOR SHRUBS
WIRE BOUND PATENT. Over 19 prizes. R.H.S. Medal, 1910. No warping shrinking. In Oak, Beech, Teak, etc. Highly decorative. — Price List from A. PRADA 26, Goodge Street, London, W.1.

ALPINE PLANTS, BORDER PLANTS, CHOICE FLOWERING SHRUBS, MINIATURE CONIFERS, HARDY HEATHS, HARDY FERNS, CLIMBERS. One of the oldest, and perhaps the finest, all-round collection in the country.

We grow some 4,000 kinds of all the best outdoor garden subjects, including such items as 100 kinds of Michaelmas Daisies, 100 kinds of Campanulas, 50 kinds of Hellebores, 200 kinds of Saxifrages, etc.

Our Catalogue of these is beautifully illustrated, shows how to build a rock wall and water lily pool, and tells about soils, etc., etc. It makes a fine reference book on plants. It is sent post free for 1s. which may be deducted from orders.

AUTUMN and WINTER BEAUTY
In the Garden.

WHEN the first Autumn frost has killed the Summer flowers and the last rose is just existing, many people imagine that the garden must be a dull uninteresting place until Spring awakens the early Daffodils.

There are, however, many trees and shrubs which will provide beautiful pictures throughout Autumn and Winter when rightly placed.

What is more beautiful than the setting sun lighting up the berries of the Cotoneasters, Thorns, and other berried shrubs; or the crimson stems of the Scarlet Dogwood, yellow and crimson barked Willows.

We have prepared a short supplement to our general catalogue, giving a list of the best trees and shrubs for Winter beauty, with fuller descriptions and cultural notes. A copy on application. We devote the same care and thought to the cultivation of our immense stocks of FRUIT TREES, ROSES, ALPINES, HARDY PERENNIALS as we do to the SHRUBS.

MAKE THIS WORK YOUR GUIDE, PHILOSOPHER AND FRIEND.

THE

GARDENER'S ASSISTANT

By **WM. WATSON, F.R.Hort.S.**

IT is **THE** Scientific work on gardening, and is the most important book ever published on the subject, in fact, it is regarded by gardeners as the **STANDARD WORK**. The editor, Mr. Watson, F.R.Hort.S., late Curator of Kew Gardens has been assisted in his task by 22 specialists—each an expert on the subject he writes upon. There are hundreds of text illustrations in addition to a magnificent series of full page coloured plates. Each branch of horticulture and its allied subjects has a definite section of its own, and each section is correlated by cross-reference wherever needful. It is written in plain every-day language. The information is clear, concise, and on unimpeachable authority, and thoroughly justifies its claim to be a work of deep interest and importance to everyone connected, professionally or as an amateur, with gardening.

A BOOK WITH A GREAT REPUTATION.

A CUSTOMER WRITES:—
Redruth, 28.12.25.
"One cannot fail to strongly recommend the books to garden lovers, professional or otherwise. I have seen nothing yet to approach them for definite instruction and description."
(*Signed*) H. E. T.

READ WHAT YOUR PAPER SAYS:
It appeals to all who garden, professional or amateur. The former will find it of the greatest possible use in supplying a ready and satisfactory answer to all those detailed questions which crop up with marked persistency in the carrying out of gardening duties.
To the amateur it comes like the Waverley Pen, as "a boon and a blessing."—THE GARDEN.

OTHER PRESS VIEWS.
The work is one that should find a place on every gardener's bookshelf, to be "read, marked, learned and inwardly digested."—GARDEN LIFE.

The "GARDENER'S ASSISTANT"—like Goldsmith's immortal schoolmaster—"allures to brighter worlds and leads the way."—GARDENERS' CHRONICLE.

It is unnecessary for us to recommend the work to garden-lovers, amateur or professional. They know it already.—GLASGOW HERALD.

It is the gardeners' whole library in six complete volumes, a work which no gardener, amateur or professional, can dispense with.—LIVERPOOL COURIER.

THE WORK IS COMPLETE IN SIX HANDSOME VOLUMES TASTEFULLY AND STRONGLY BOUND, A CHARMING EXAMPLE OF PRINTER'S ART.

A Prolific Garden

cannot be maintained without the aid of some kind of manure. Stable manure is now scarce, and is bulky to cart and spread on the land. No artificial will altogether take the place of natural manure, but a good well-balanced fertiliser, used during the growing season, is a wonderful aid in producing high-class garden crops. No fertiliser is cleaner, more effective, or economical than

PEARSON'S CHEMICAL MANURE

which is compounded from the purest chemicals. It contains every element necessary to plant life which is not present in any ordinary garden soil. A glance at the analysis will prove that this manure is as cheap as any on the market, while nothing can beat it in ease of application and results.

ANALYSIS
PEARSON'S "CHEMICAL MANURE"
(ARTIFICIALLY COMPOUNDED)
Contains at least 11·70 *Phosphates, soluble and insoluble;* 6·68 *Potash;* 6·44 *Nitrogen* (*Ammonia Nitrogen* 4·56, *Nitric* 1·88).

Per cwt. 25/-, ½ cwt. 13/- carr. paid. ¼ cwt. 7/-, 14 lb. 4.6, 7 lb. 2/9, carr. forward.

THE EFFECT OF SPRING

SPRING is supposed to affect everything living in a cheerful fashion. Lambs gambol; horses cavort; hardy mortals leave off their thick woollens; and poets ransack their dictionaries for appropriate words. Very important is the thrilling effect that the first warm days of the year have upon most gardeners: in one of his letters Farrer speaks of the throb of spring. "Don't I know it? For that is what always turns my heart to the hills in June, and what, in the first warm day of March, sets me itching to get my fingers into the vibrations of the awakening earth: why, it is like running one's fingers through the hair of La Belle au Bois Dormant as she stirs from sleep!" That is perhaps more poetically expressed, but it is what every lover of the countryside and of flowers feels deep down in his being. Sometimes this feeling is like a slight touch of malaise: you are restless; you mope, if you are cooped up in a city; you want something vaguely and have no idea what it is. If you only knew, it is Nature asserting herself. When first I was buried in a city, I knew not what it was: now I am wiser.

To some like Farrer—and I must be included among them—even a garden is not quite satisfying; it savours too much of man's handiwork. We long to be primitive and rush away in solitude to the wilds and dig our fingers into the vibrations of the awakening earth. Unfortunately for me, at least at the present moment, this is impossible, and I have to be satisfied with what I can get. But let me advise all who can to revitalise themselves by putting a "jeely piece" in their pocket and making a solitary excursion on the first warm, fine morning to the loneliest part of the countryside within reach, and there spend the day in peace and solitude. It is good for body and soul alike.

Then, as I am writing for horticulturists, let me suggest that you walk around your gardens in the late afternoon and with peace in your soul and the blood coursing through your veins see if it comes up to your expectations. If it does, well and good, for it is *your* garden and other people's opinions are of no importance. If it does not, just think slowly and serenely wherein the fault lies. For me, there is no time like the first days of spring for using my imagination in the garden. In the autumn I look upon the dank soil with the cold of winter in front of it with something very close to actual distaste. In the spring I view the soil with a kindly feeling and smell the re-awakening earth, a very kindly scent. Once in this frame of mind all is well, for, after all, the soil gives most things to a plant, and those who love the soil and like to dig their fingers into it go a long way to understanding life, as it affects a plant, a subject that is not taught in text-books.

There is little use trying to copy Nature so closely that you must have your bank smothered in primroses or a swathe of thin woodland drenched with bluebells, or, earlier in the year, acre upon acre snow-white with snowdrops. Probably, if you did, you would not be successful, for Nature is occasionally jealous and likes keeping some things to herself; but there is a happy mean: everyone should aim at, not Nature's garden, but a natural garden. There is a world of difference between the two. Some plants are complacent enough to look well in almost any position; some require immense care; most of them lie between the two extremes. In all cases they should look as happy as possible. In my opinion, the gardener can do more in arranging his plants in the spring than at any other time of the year. It may be imagination, but to me it seems as if at this time of the year they fall more naturally into their places. If one likes what the earth brings forth, one is better tuned to catch the earth's throb at the awakening of spring.

This may appear to be an odd note on which to begin a number that ought to help gardeners in the important matters of what to plant in the spring and how to plant it; but there is sometimes something lacking, something that is not entirely matter-of-fact and which yet has a great influence on successful cultivation. In successful gardening a little imagination and a little understanding are almost as important as skill and knowledge. That is my excuse.

E. H. M. C.

AMONG THE ARTICLES IN OUR NEXT ISSUE WILL BE:

A RHODODENDRON TOUR.

CARNATIONS OF THE FLORISTS' SHOP, by Montagu Allwood.

RHODODENDRONS IN WIND AND DROUGHT, by W. Arnold Forster.

FRAGRANCE IN ALPINES AND WATER PLANTS, by H. W. Canning-Wright.

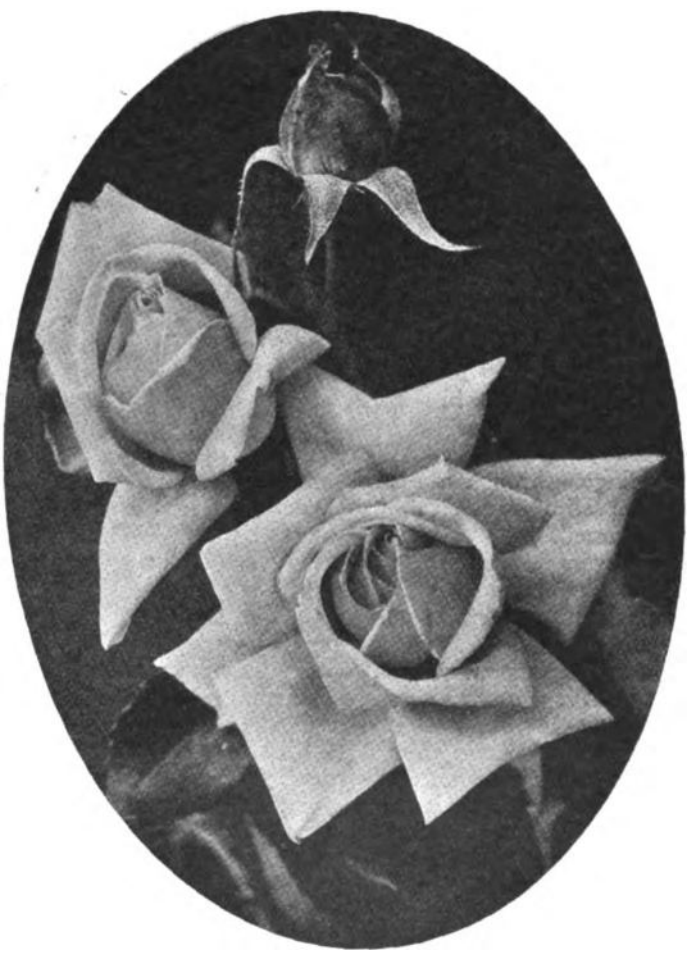
A SELECTION of ROSES for SPRING PLANTING

THIS should be one of the busiest spring planting seasons on record, for the weather during last November was so unpropitious that most of the work of late autumn was left over until the new year. Favourable weather conditions, that have prevailed in most districts during January and February, have seen much of the lost ground made up, but there must be many growers who have not completed their planting, and it is to these that I offer a few suggestions.

Each season sees the decorative type more firmly established as the most popular as well as the most useful class of rose. The exhibitor is in the minority, and it is perhaps quite safe to say that at least 75 per cent. of rose enthusiasts favour the free-flowering type. Our leading raisers are alive to the importance of public demand, for the majority of novelties now introduced possess some claim to be regarded as useful garden varieties. Strong, or moderately strong, branching habit, as well as free-flowering capabilities, should be a desideratum of any novelty that is likely to hold its own as a popular introduction, and if there is fragrance in addition, so much the better.

FAVOURITE DECORATIVE VARIETIES.

There are many names that come readily to mind when one is compiling a list of popular decorative varieties, and readers will need no introduction to such well known kinds as Caroline Testout, Mme. Abel Chatenay, Lady Pirrie, Ophelia, Mme. Butterfly, General McArthur, Mrs. Henry Morse, Los Angeles, Golden Emblem and others that have firmly established themselves in public favour. Most of these do well in any locality, and this partly explains their immense popularity. The test of a variety is really settled by the rose-growing public, and it is safe to say that public opinion is the best selection committee. Many of our gold medal roses have made good after being placed in commerce, others have disappointed. Sometimes a variety that has received no awards proves itself to be a good garden rose. While it is perfectly fair to assume that a variety must have some outstanding features to secure the highest awards, it is well to understand that all gold medal varieties cannot be relied upon to give entire satisfaction for all purposes. It sometimes happens that a gold medal rose is better for exhibition than for general garden cultivation, while many varieties that secure the premier award at the spring show are ideal for cultivation under glass, but useless out of doors.



THE RICH YELLOW ROSE SOVEREIGN.

SOME NEWER DECORATIVE VARIETIES OF MERIT.

I do not propose to discuss any of the well known kinds, but will confine my remarks to a few of the newer introductions that I have found reliable.

Betty Uprichard is a comparatively new variety that has come to the front by leaps and bounds. It deserves its high place in public esteem, for it is a delightful decorative rose. Mr. Alexander Dickson, who has probably seen more of this rose than most of us, told me two years ago that he considered it the best decorative variety, taking one season with another, that we have. This is high praise, but Mr. Dickson is not far off the mark, for Betty does not seem troubled by the wet, and in sunny weather, even if the blooms are somewhat fleeting, they retain a certain amount of beauty of form long enough for us to enjoy them. The rich carmine is suffused with orange so that there is no crude colouring, and the lighter facing of the petal gives that striking contrast which adds to the variety's distinctiveness. The only rose of this colouring that we had previously seen was Edith Part, a very pretty variety that is still worth growing, but the richer tones of Betty Uprichard, together with its strong, branching habit, combine to make it a better rose. It also has quite a moderate degree of fragrance.

Shot Silk, from the same firm, promises to be a fine rose if it has a sufficiently strong constitution. It is not quite as robust as Betty Uprichard, but it is certainly far from being a weakling. The colouring is glorious and the blooms possess good form, and sufficiently full to open in all kinds of weather, and there is fragrance. It should make a good bedding variety, and doubtless will be planted in large quantities when it reaches a normal price.

There seems to be a divided opinion as to the merits of Mabel Morse as a decorative variety. It is not a particularly strong grower with me, but in other districts, especially in the west, I believe it is quite satisfactory in this respect. The blooms are full, invariably of good form, and they rarely come "quartered," as is often the case with Golden Emblem. As a decorative yellow I prefer Florence Izzard, which appears to be almost a yellow Chatenay. The blooms are not as fine specimens as those usually found on Mabel Morse, but they are produced on long stems and have fairly good lasting qualities. There are good points about all these three yellows from Portadown, and in certain respects one has a pull over the other. An ideal yellow would combine their best characteristics. Until it comes along the best plan is to grow all three.

Another good yellow that has come to the fore is Messrs. B. R. Cant's gold medal variety that bears the honoured name of the Rev. F. Page Roberts. It has been the aim of raisers for many years to produce a rose suitable for outdoor culture that carried the colouring of the old favourite, Maréchal Niel. Although it may be rather a bold assertion to make that this has been achieved in the rose in question, we may safely say that it approaches very nearly the ideal. The blooms are of good shape and carried erect on long stout stems; the habit is vigorous and there is a pronounced fragrance. I have no doubt that Rev. F. Page Roberts will become still more popular.

Another yellow from the same firm is the delightful little bedding variety that bears the descriptive name of Sovereign. Some of us, with memories of the gold coin that used to jingle (usually all too rarely), in the days before the advent of paper money, might find some pleasure in the comparison, and enjoy the lustrous and metallic sheen of the flower, the rich colour of which is retained till the petals drop. Sovereign is rather diminutive in habit, but it makes a capital bedder where one does not require the taller, branching type. It is one of the freest of all the decorative kinds, and Messrs. Cant's tell me that in their nurseries there is more bloom

Digitized by Google

per plant on Sovereign than on any other variety. Its lovely, shining foliage is also an asset, and it is, naturally, mildew proof.

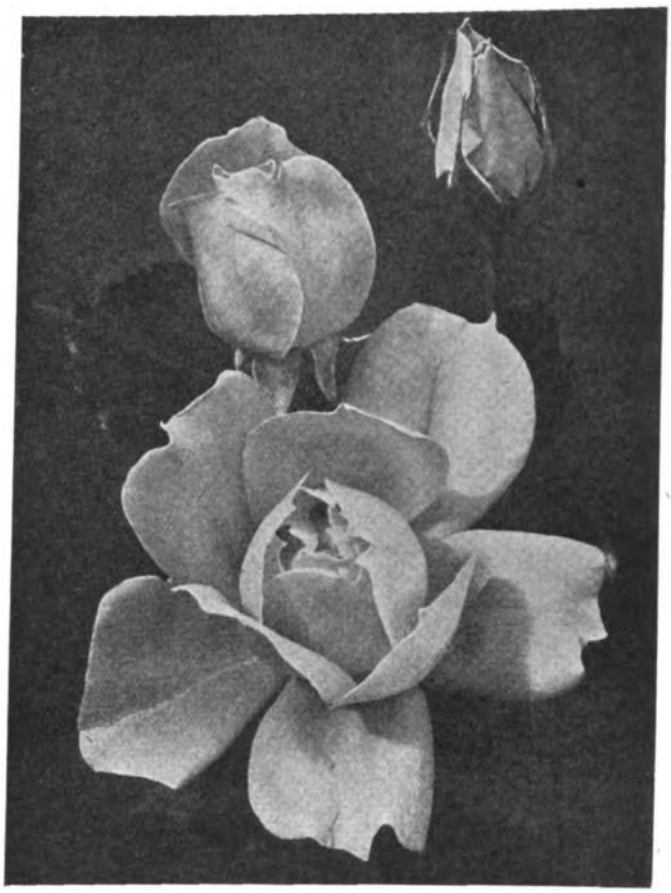
A fine rose for all purposes is Captain Harvey Cant, a beautiful salmon pink of splendid build and good lasting qualities, from Messrs. Frank Cant's Braiswick Nurseries. It has a strong, erect habit and the blooms are carried on long stems. Mrs. Alfred West, a rich salmon pink in the finished flower, is another splendid rose from the same firm. The blooms are full, finely formed and very lasting. In these days of so many pink varieties it is well to remember these two out standing salmon pinks from Colchester.

I have a very high opinion of the merits of Mr. Easlea's beautiful variety, James Walley. It is a splendid grower with a strong, branching habit, lovely foliage and long flower stems. The blooms are Ophelia-like in form and colouring, but there is a richer colour tone—shades of yellow and apricot—in the heart of the bloom. The flowers are of perfect formation from the bud stage to the half open bloom, and in autumn they open into large, shapely, full flowers.

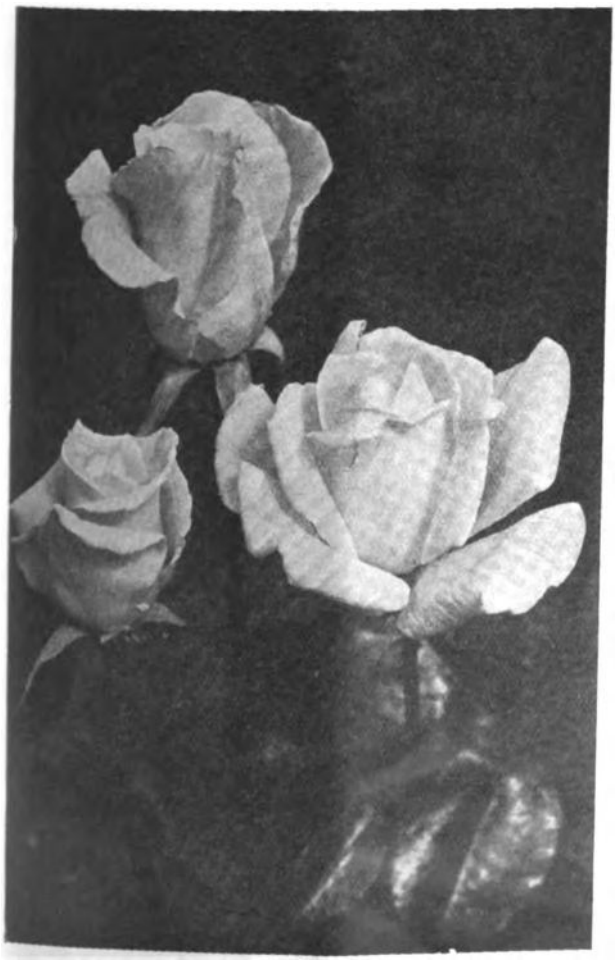
A rose of somewhat similar shape and colouring is Vanity Fair, one of Messrs. Dobbie's introductions. In the colouring there is certainly some resemblance to Ophelia, but the habit and foliage are reminiscent of Joseph Hill, which was probably one of the parents. Vanity Fair is a good autumnal.

Two useful crimson roses that deserve a place in every up-to-date collection are Etoile de Hollande and Lord Charlemont. The former is a Continental introduction that is now becoming very popular. It is a deep, velvety crimson that carries full perfume and the blooms are freely produced. They are pretty in the bud and half-open stage and make good buttonholes. The growth of the plant is sturdy and the foliage is handsome, and as far as I have seen, mildew proof.

Lord Charlemont is a grand clear crimson that will become a favourite for bedding or massing. It is strong in growth and the flowers, which are of good form, are freely produced.



THE BEAUTIFUL AND SHAPELY BLOOMS OF ANGELE PERNET.



THE DECORATIVE MUSTARD YELLOW FLORENCE M. IZZARD.

Though not as strongly scented as some of the other crimsons, it has a delicate perfume. Another good crimson from Portadown is Arthur Cook, a very sweetly scented and promising variety. When better known it is likely to become a popular rose.

I have been very pleased with the Rev. Joseph Pemberton's prettily coloured variety named Ruth, in which there is a subtle blend of orange and carmine. The flowers are full and of good form and the plant appears to have plenty of vigour. It is a variety that will increase in popularity.

Both the cerise varieties, Lady Inchiquin and Mrs. Courtney Page are noted for their purity of colour, and where they will grow well they can be recommended. They are sunshine roses and delight in a fine, dry summer.

Other useful varieties that are worthy of a trial are Admiration (cream shaded with vermilion), a fine decorative rose; Doris Trayler, shades of orange, yellow and red; June Boyd, shades of carmine, yellow and amber, changing to peach; Souvenir de Georges Pernet, a fine bold bloom of somewhat unique colouring in which there is a mixture of Orient red and yellow; William F. Dreer, a soft blend of golden yellow and peach shades, identical in habit with Los Angeles; and Souvenir de Mme. Boullet, a fragrant dark cadmium yellow with long, elegant buds and large, full flowers. The new Pernet-Ducher production, Angele Pernet, is a lovely bit of colour and promises to be useful as a decorative variety, but it is somewhat thin and rather short in the petal. It is, however, impossible to judge it on one season's test, and we may find it better in 1926.

Those who try the novelties, too, will probably find several acquisitions among them, and one expects great things of Gwyneth Jones, White Ensign, Empire Queen, Barbara Robinson and Dame Edith Helen. I have just received a note from Mr. Alexander Dickson and his comments on Dame Edith Helen are: "This will be the best of our new set. It is a real outstanding rose full of good points."

The forthcoming season—the Jubilee Year of the National Society—will probably see the advent of many new fragrant roses, and the autumn introductions should include several decorative roses of merit.

NORMAN LAMBERT.

THE MODERN BORDER CARNATION

THE planting of these hardy border subjects can be carried out within the next few weeks. In one of Bacon's essays he tells us that in July we may expect to see gilliflowers of all kinds in bloom, and it is interesting to observe that the old gilliflower is still with us, although the gilliflower or carnation of to-day has made great progress since Bacon's time.

Now we have a race of carnations hardy and able to withstand, without protection of any kind, the wet and cold, and the rapid changes of temperature to which we have become accustomed; while, at the same time, when the summer comes, the flowers are found to be incomparably superior to those which graced our gardens a few years back. We find now that the border carnation of to-day is hardy, that the flowers have been developed until their colouring, shape and size are upon a much higher level than ever before, and that such faults as weak stems and split calyces have been practically eliminated.

Bearing these facts in mind, it is a little difficult to understand why the border carnation is not more generally grown, and the only possible solution seems to be that the average gardener confuses it with the perpetual-flowering type which needs protection in winter, and has failed to realise that plants can be put out in the autumn and left without any protection at all until they come into bloom in the following June and July. There is every evidence, however, that this misapprehension is being rapidly dispelled and that soon border carnations will be grown extensively, not only by those enthusiasts who appreciate their many wonderful qualities but by everyone who possesses a garden.

Border carnations may be obtained either as rooted layers in the autumn and planted in their permanent quarters without delay, or, alternatively, they may be purchased ex pots in the spring and planted out in late March or early April. Each method has its own following and there is a lot to be said for both. While I myself prefer to plant in autumn if possible, very successful results can certainly be obtained from planting in spring, and, if the plants are obtained from a good grower who will take care not to disturb the roots, they should grow right on without any harm being done. Spring planting has many advocates, and this is evidenced by the fact that those trade growers who specialise in carnations always dispose of as many, if not more, plants in the spring than in the autumn.

It would have been as well if a bed had been prepared in the autumn to receive the plants; but if this was not possible, the ground would probably benefit from a good dressing of slaked lime, for carnations like lime and will flourish where it is found. I have always found ground garden lime very satisfactory, as it is easy to handle.

Assuming, then, that the ground is ready, the plants should be firmly planted 15ins. apart, allowing 15ins. between the rows, and, if it is possible to put sticks for support in place without delay, all the better, for then there is less chance of disturbing the young roots later on in the spring. Cane or light sticks are best and quite strong enough to support the plants. While on the subject of tying, I feel that I must make a brief reference to this necessary but irksome work. Many growers, apparently, continue to use raffia for tying, but I cannot advocate too strongly the great advantage of split rings made from galvanised wire.

Just one more word regarding spring cultivation. One of the most useful

CARNATION VICEROY, A FINE YELLOW-GROUND FANCY.

tools in the tool-shed is the Dutch hoe, and, where carnations are concerned, it is invaluable. I have found hoeing most beneficial, as it keeps the ground clear of weeds and, more important still, renders the surface sweet and fresh. The successful carnation grower uses the Dutch hoe on every possible occasion, and the result of its continued use soon becomes evident.

Such progress has been made in the evolution of the border carnation in the last few years that I should like to say a few words on the different varieties obtainable. A wide range of colours is embraced, and perhaps the most useful way would be to give a list of really good varieties which are suitable for border cultivation.

Among the selfs the following can be recommended as good strong growers:

White.—Elaine, Bookham White.

Yellow.—Mary Murray, Border Yellow, Eldorado.

Scarlet.—Veldtfire, Grenadier.

Crimson and Maroon.—Joan Wardale, Gordon Douglas, The King.

Orange.—Dr. R. Crawfurd, Elizabeth Shiffner, Loyalty.

Lavender.—Yvonne Thomas, The Grey Douglas.

Pink and Rose.—Bookham Rose, Salmonea, Lady Hermione.

The yellow ground fancies offer a wide selection, and the following are all very good: Centurion, Linkman, Viceroy, Pasquin, David Stobart, Mrs. J. L. Gibson, Lady Shackleton, Sheila Gibson, J. Saville and Dr. Stone.

It is probably the white ground class which has made the greatest progress of late. The following three varieties are particularly good: Mrs. E. Charrington, Steerforth and John Stobart.

Other good kinds are: Jessie Murray, A. St. Clair Amos, Mrs. G. D. Murray and Mrs. Hawksbee.

There are also one or two varieties of fancies which cannot be included in the two classes already mentioned, in that they have neither white nor yellow grounds, and the two most notable examples are James Griggs and Sam Griffiths, which have cerise or rose markings on a lavender grey ground.

Those growers who insist on a strong scent in their flowers will probably find their requirements more than covered by the clove-scented class, which embraces such well known varieties as Steerforth, to which reference has already been made, Pearl Clove, Fragrance, Doris Trayler, Blush Clove and Salmon Clove.

In closing, let me make a brief reference to the yellow ground picotees. These beautiful flowers have never received the attention that they have deserved in the past, and it is difficult to understand why, for they are quite hardy and deserve a place in every garden. Her Majesty, Mrs. J. J. Keen, Margaret Lennox and Togo are all good, and once they have been tried they are not likely to be discarded again.

ANGUS BENNETT.

VIOLAS FOR PRESENT PLANTING

PANSIES and violas are not only becoming increasingly popular, but the newer introductions contain a large number of improvements on older sorts which denotes progress in hybridisation. Our leading raisers, too, are realising the importance of producing novelties that have both a good constitution and a neat, tufty habit. Both these are important considerations from a decorative point of view, and as the great majority of growers require pansies and violas for garden decoration, this is a step in the right direction. Our Scottish friends number among their enthusiasts many expert growers, and here the system of staging on boards is paramount; but there are also several champions on this side of the Border, where the method of staging in small tubes fitted into sand-filled pans covered with moss—a method that is commonly known as "vasing"—is in favour. For the latter purpose the long-stemmed

Digitized by Google

flowers are necessary. For showing on boards a bloom that lies flat is preferred.

THE DECORATIVE TYPE.

For garden decoration the free-flowering bedding type is best. These have smaller flowers than the exhibition sorts, but they are more freely produced. The habit is dwarf and compact, and a young plant will, by autumn, grow sufficiently round and tufty that it can hardly be covered with an ordinary sized basin. If trimmed and left undisturbed it will generally survive the winter and, as a two year old, give a brilliant display of bloom the second season. A further supply of plants can be raised from cuttings or a division of the older plants.

Some of the larger-flowered types have a fairly compact habit, and those that are of a strong constitution can be used effectively for bedding purposes, although as a rule they are not so eminently suited for the purpose as the purely bedding type. Pansies, too, consist of two kinds. There is a bedding type that has a neat, compact habit, and the rich colours of these—shades that are not found among the violas—are very striking. The varieties that are used for exhibition include fancy pansies and show pansies. The former are general favourites, being large-flowered, with a central blotch and markings or suffusions on the upper petals. The lower and side petals have margins—white, cream, yellow and so on—and these should be regular and clearly defined. The show pansy is much smaller, with a lesser blotch. It is very pretty, but during late years it has not been widely cultivated, and it is doubtful if it will ever again become very popular.

SELECTING A SITE AND PREPARING THE SOIL.

Pansies and violas like an open situation that receives some protection from the full glare of the sun in summer. If this can be provided by an adjacent wall or from trees that are near but not overhanging the beds, so much the better; but if not, then it is sometimes necessary to shade the plants if the weather continues to be hot and sunny. A mulch will often answer the purpose of conserving moisture during the summer drought, but it is better to provide the beds with a good foundation of well rotted animal manure before the plants are put out. The sooner this is done the better, so that the beds have sufficient time to settle down. The animal manure, together with a little bone-meal, superphosphate, wood ashes and soot, should be worked into the soil as digging proceeds. Do not let the beds lie too low, especially if the garden is a shady one. In this case it is better to raise the beds a little. Very little damping off or stem rot results if plants are grown on slightly raised beds.

V. MRS MARRISON, A STUDY IN CHOCOLATE AND ROSE.

VIOLAS IN THE SUMMER BORDER.

A SELECTION OF BEDDING VARIETIES.

The best white bedder is Swan, a rayless pure white variety with a conspicuous orange eye. It is a capital grower with a splendid tufty habit, and it is very fine the second season if left undisturbed. In cream selfs there are Lady Knox and Cream King. I prefer the former. In the yellows there is a wide choice, from pale primrose to deep orange. Margaret Wood, Royal Sovereign, Moseley Perfection, Mrs. C. B. Douglas, Bullion, Kingcup, Klondyke, Redbraes Yellow, Walter Welsh and Tangerine are all good, most of them having a tufty habit. Mauve shades also give plenty of choice. The most popular are Maggie Mott, John Quarton, Mauve Queen, Kitty Bell, and Fred Williams. W. H. Woodgate is a pretty light blue, and Archie Grant Improved one of the best dark blues. The finest purple is Royal Purple, an improved Councillor Waters. In the edged varieties James Pilling, A. S. Frater, Gladys Finlay and Pride of Darras are all reliable. The two last-named have deep purple beltings. One of the prettiest fancies is Dunbryan, a soft shade of heliotrope suffused over a white ground; and Mrs. Marrison, with its chocolate and rose marbling, is very striking.

Digitized by Google

Some of the best of the larger-flowered kinds that can be used for bedding are Master Bankes (lemon yellow), J. V. Macdonald (white), Mrs. J. Scalley (white, edged with blue), Jean D. Cowan (chrome yellow, edged and suffused with mauve), John Adamson (orange), Mrs. W. R. Milligan (white, with a thin wire edge of pale blue) and Peace Fold (creamy white).

POPULAR EXHIBITION VARIETIES.

The following are some of the most popular of the standard exhibition kinds: William Barr (white), Mrs. Andrew Stevenson (yellow, edged with violet mauve), John Adamson (orange), Chriss Littlejohn (white suffused with lilac), Mabel Spencer (white, with blue edge), Mrs. J. Ritchie (white, with faint edge of light blue), Lily Stark (deep violet, with lavender top petals), Kathleen Condry (deep purple), William Gibb (primrose self), Malcolm Milner (deep primrose, edged with blue) and Annie Hamilton (glossy black shading out to lavender).

NEWER VARIETIES AND NOVELTIES.

In the newer introductions that have not yet had time to become very popular, Mrs. William Boyes (lemon yellow, edged with lavender), Jenny Simpson (lemon self), Mary Douglas (cream, edged with mauve), Sheila Mathews (cream suffused with rosy mauve), Smith's Purity (white), Mrs. Adam Young (cream, edged with pale lavender), Rowan Hood (chrome yellow, belted with lavender) and Andrew Jamieson (a fine striped variety) are all promising. The novelties for 1926 include many outstanding sorts. The best are Moseley Ideal (a beautiful canary yellow edged with blue), Mrs. H. J. Milner (a splendid white ground edged with bluish heliotrope), James Sievewright (white, with a distinct band of deep blue), Mrs. A. C. Thomson (cream, with a heavy band of light heliotrope), Jeannie Rutherford (lemon, edged with mauve), Etta Shaw (white, with deep violet band), Mary Watson (cream, edged and suffused with reddish lavender), Helen W. Cochrane (a very notable advance in the white varieties) and Harry McDougall (a beautiful yellow that has long stems).

YORKS.

THE HERBACEOUS BORDER IN SPRING

MARCH is an excellent month—particularly, of course, in the event of a spell of hard-bound winter, or of excessive saturation—for planting such herbaceous plants as could not, for various reasons, be planted in autumn. Indeed, many plants will move with practical certainty of success in March which are by no means safely transplanted in November. Scabiosa caucasica is one among the considerable number of plants which are seldom successful when planted late in autumn, that, in fact, being the principal reason so many people have to confess they have failed to establish this much desired plant, the supplementary reason being that the majority of people will crave for "strong clumps," and the scabious is one of those hard, woody rooted, yet sappy plants which move very badly when once they have firmly established themselves. Quite young plants, either propagated from crown cuttings or from seed, will go ahead comfortably when planted in March.

A PLEASANT ASSOCIATION OF BLUE DELPHINIUMS AND PINK ROSES.

Alstrœmerias ought never to be disturbed in autumn; at the best they are extremely impatient of root disturbance and the two surest methods of establishing a good bed are by sowing new seed very thinly on the site which is to be their permanent bed (and, of course, thoroughly well prepared by extra deep digging), or by planting young stock which has been grown for one season from seed in pots. These plants may be put out in March and a very good method, if the natural soil inclines to heaviness, is to dig out holes 18ins. deep, having first double-trenched the whole area, place 6ins. or 8ins. of rough, gritty compost, burnt earth, etc., in the bottom of the hole, then place the pot-ball unbroken upon this compost and surround and cover it with a mixture of light loam, leaf-mould and sand. Alstrœmerias are better allocated to a bed by themselves or to a corner of the border where they are not brought in close contact with surrounding plants. They should be looked upon as a permanent feature and if occupying the middle part of a mixed border they will either encroach upon other plants or suffer during necessary periodical renovations.

Lupins and delphiniums both transplant so well in March that it should be the recognised month for the task. When one is planting fresh stock from the nursery the plants are usually small enough to go into the ground as they are, but where one's own stock undergoes a triennial upheaval, and neither lupins nor delphiniums should spend longer than their third season undisturbed, transplanting must be rather an elaborate business if the finest results are to be secured.

Let it, in the first place, be understood that in lifting either of these subjects it is the tips of the smallest young roots that will be of greatest service in re-establishing the plants. It is folly, therefore, to wrench the plants from the ground, levering them out by pressure on the handle of a fork or spade; by such means the really valuable portion of the roots will be torn away. Dig well round and carefully lift the clump. The next step is to remove soil from the roots with the aid of a pointed stick, until the junctions of main roots, with the solid root stock, can be discerned. The plant is then ready for division. The object should be as nearly as possible to separate individual crowns with a fair proportion of healthy young roots attached. This may sound quite simple, but the unpractised hand will find it is terribly easy to break away the majority of the good crowns with little or no root, and ultimately to leave the great mass of roots united but almost destitute of crowns. The beginner will be well advised to try his hand first on a few common old plants and should certainly master the task before mutilating a Millicent Blackmore delphinium or a Goldcrest lupin. I have found the best implements for dividing big clumps to be a couple of chisels of good length and strength and with good handles. One may usually find a spot where the clump may be laid upon its side without breaking

Digitized by Google

crowns, and in such a position that the two chisels may be placed close together midway between principal crowns. With careful pressure the chisels are driven through the trunk or main body of the root stock, and then by very gently levering the handles in opposite directions the clump is split in two comparatively even pieces. Examination will now show where the next divisions may be made, using a strong knife in such a way that the crown remains at the top of a substantial piece of root stock, with as much fibre as possible attached thereto. Do not leave badly torn pieces of root stock untrimmed. Dust over all torn or cut surfaces with finely powdered charcoal and the pieces are ready for planting. Make holes large enough to let the roots comfortably into the ground, that the base of the young shoots is about level with, but certainly not above, the normal level of the ground. Spread the young roots out in a natural manner and let some fine soil trickle among them. Pack well round the crown of the plant and if the natural soil is heavy, use a lighter, gritty mixture close around the roots. Lupin roots should be covered with a white, slimy-looking substance and have numerous little pea-like nodules attached to the roots. Many inexperienced gardeners imagine this to be some fungus or disease and endeavour to remove it, but this is wrong; the apparent disfigurement is natural to lupins and other leguminous plants and must be allowed to remain.

It is unwise to disturb growing bulbs in borders at this season; but all the summer and autumn flowering perennials, such as phloxes, heleniums, erigerons, Michaelmas daisies and many other kinds, will repay overhauling. Any plant which makes a lot of separate crowns with a direct attachment of young roots will yield the best results if pulled apart and replanted singly, distributing the pieces evenly over an allotted area instead of placing three or four dense clumps at 2ft. apart as is so frequently advised. Rhizomatous plants, such as aconitum, liatris, doronicum and polygonatum should not be planted deeply; let the rhizome be close to the surface, and when planting is completed, mulch with about an inch of sifted, gritty compost which rains will wash into the little cavities and crevices which settlement is bound to cause.

Old stools of aquilegias, hollyhocks, verbascums, Gypsophila paniculata, eryngiums, echinops and Coreopsis grandiflora, are not really worth transplanting. One year old seedlings are always more satisfactory, but the sterile hybrids of perennial verbascums and the echinops, as well as eryngiums, should be propagated from root cuttings.

Kniphofias transplant better now than at any other time and the pampas grass, the asphodels, anthericums, incarvilleas, platycodons, Asclepias tuberosa, Dictamnus fraxinella, Baptisia australis, Thalictrum dipterocarpum and Romneya Coulteri all take kindly to fresh quarters when planted during this month, which gives them time to lay hold of the soil before the possibility of a spell of drought such as we frequently experience when spring is merging into summer. A. J. MACSELF.

SHRUBS FOR WALLS

BY W. J. BEAN.

(Continued from page 155.)

THE splendid evergreen, BERBERIDOPSIS CORALLINA, with its leathery, dark green, toothed leaves up to 4ins. long, and its long, pendent racemes of rich blood-red flowers, is one of the most beautiful climbers in cultivation. It is undoubtedly better suited (like so many Chilean plants) for the soft, south-western counties than it is for our average climate, where, nevertheless, it can be grown on a sheltered wall; not, however, exposed to full sunshine. It might even be tried on a north, or preferably north-west, wall and given some protection during very severe weather by means of a glass light if possible. As far north as Northumberland it has been successfully cultivated in this way. Failing a glass covering, one of light canvas might be used. It flowers from July onwards. When it has filled its allotted space it may grow in a tangle, reducing it only when it gets too heavy.

BERBERIS.—Two species belonging to the mahonia section of this genus are sometimes grown on walls. They are B. Fremontii and B. trifoliolata, both from the south-western United States and both with vividly glaucous foliage. The former has five or seven leaflets to each leaf, the latter as its name implies, only three. Both have yellow flowers and black fruits covered with a blue bloom. They must have as sunny a position as possible and are rather for lovers of rarities than for general cultivation.

BIGELOVIA GRAVEOLENS.—An interesting shrubby composite from western North America, growing 6ft. to 8ft. high on a wall; it has grey young shoots and very narrow leaves 2ins. or 3ins. long. The flowers are bright yellow, densely clustered at the ends of the current season's shoots, and open in September and October. It likes a sunny wall, but has succeeded very well at Kew on one with an eastern exposure.

BILLARDIERA LONGIFLORA.—This charming evergreen climber, with its slender stems, its narrow dark green leaves, its yellowish flowers and its rich blue fruits, is becoming better known and has several times lately been shown at Vincent Square. Probably it grows taller, but I do not remember to have seen it more than 4ft. to 5ft. high out of doors. It is, at any rate, suitable for furnishing a vacant spot at the base of a warm wall, where it may grow in a sort of tangle with little pruning. Tasmania.

BUDDLEIA COLVILEI.—So far as its individual flowers are concerned, this is the finest of all the buddleias, each one being nearly 1in. long and as much wide, of a lovely shade of rose (in one form crimson) and borne in pendent panicles 6ins. or 8ins. long. A vigorous grower, it is suitable for a lofty wall. Himalaya.

BUPLEURUM FRUTICOSUM.—Of interest as being the only shrubby umbellifer we can grow out of doors, this is not without beauty either. It has long been grown on the old walls at Kew, where it is 10ft. high. Its blue-green leaves, rather like those of a large-leaved spurge, and its small yellow flowers in umbels 3ins. or 4ins. wide, make an effective contrast from July onwards.

BURSARIA SPINOSA.—In Mr. P. D. Williams' delightful garden at Lanarth in Cornwall this is a very elegant small tree, being perhaps 15ft. high, but farther north we have to grow it as a wall shrub. It is an evergreen from New South Wales and Tasmania, with small, very abundant leaves and small white fragrant flowers borne in great profusion. It has a second season of beauty when the small reddish fruits develop, each one shaped like that of the common shepherd's purse. It used to be very attractive at both seasons on a wall in Canon Ellacombe's garden at Bitton, near Bath. It is figured in THE GARDEN, October 11th, 1919, page 483.

CÆSALPINIA.—Nearly one hundred years ago C. Gilliesii was introduced from the Argentine, yet it still remains very scarce. It has doubly pinnate leaves like those of the small-leaved "mimosa," but green, not glaucous, and erect racemes carrying thirty to forty flowers that open successively, each with a rather cup-shaped corolla of yellow petals from the centre of which rises a cluster of scarlet stamens each 2ins. to 3ins. long—a brilliant combination. It is grown on the south side of No. 1 Museum at Kew and, being a tall grower, is suitable for a narrow space between windows. It must have full sunshine. Sir Herbert Maxwell told me a few years ago it succeeds splendidly in Spain. He saw it there in a deserted Andalusian garden in full flower—"a magnificent piece of firework." There, of course, it gets the sunshine it loves.

The other cæsalpinia, C. japonica, with handsome foliage and fine racemes of bright yellow flowers, is a very handsome shrub, but so thorny and unapproachable that it is unsuitable as a wall plant. It used to thrive on a sheltered sunny slope in the Coombe Wood Nursery, but at Kew we find it scarcely hardy in the full open. It has, however, for many years past, succeeded well in one of the recesses of the wall of the Temperate House facing south-east. It is best in some such place, where one can leave it alone and admire it from a sufficient distance away.

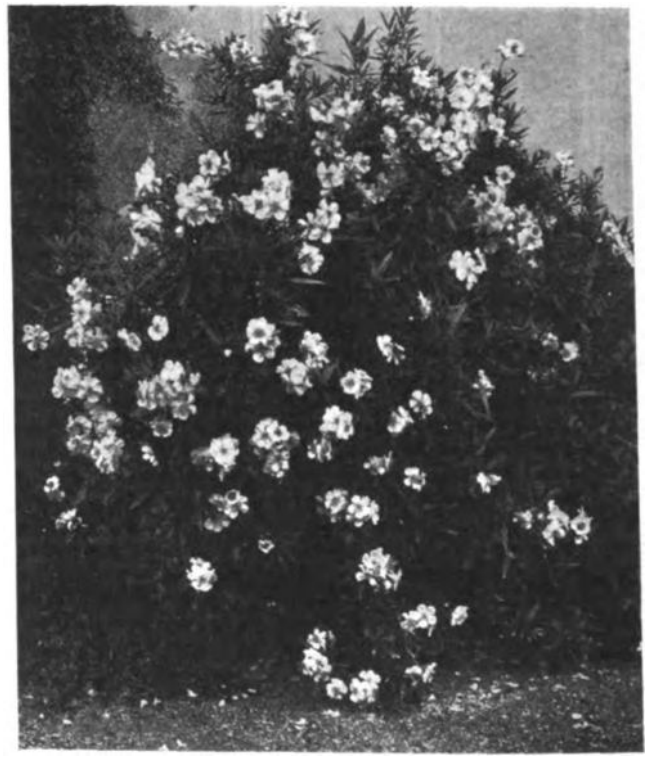
CAMELLIA.—I think the forms of C. japonica are well worth trying against a north wall. They would not flower so freely as in a sunnier place, but they do flower quite well in partial shade, and in any case would make a fine furnishing of glittering dark green foliage. C. Sasanqua would also be worth trying.

CARPENTERIA CALIFORNICA.—This charming evergreen, with its narrow, bright green leaves and clusters of pure white, fragrant flowers, each 2ins. to 3ins. wide is one of those shrubs which succeed at the base of a sunny wall, enjoying its protection without being actually trained upon it.

CEANOTHUS.—The ceanothuses possess an almost unique value as wall shrubs on account of their blue flowers. One may find a few others perhaps of that colour, but none capable of producing such gorgeous effects as they do. Coming from California, as the best blue-flowered ones do, they enjoy all the sunlight they can get in this country. Therefore a south wall is to be preferred for them, but, failing that, they may be given places on those facing east or west. The kinds most to be recommended are rigidus, dentatus, papillosus, floribundus, Lobbii and Veitchianus, all of which are evergreen and have blue flowers. The last three are natural hybrids, not very dissimilar, so one of them may suffice. Veitchianus is perhaps the hardiest of the three, and thirty miles or so south of London begins to be hardy in the open ground. It gives a wonderful display in Mr. L. de Rothschild's garden at Exbury. The typical C. thyrsiflorus is perfectly hardy at Kew with no protection at all, but its variety griseus, with larger leaves and pale grey-blue flowers, needs a wall, making there a very attractive display in late May and June. For those who like rare shrubs, C. velutinus var. lævigatus may be noticed. It has larger leaves than any other of the cultivated ceanothuses, these being heart-shaped, strongly three-veined, of a blackish varnished green, and up to 3ins. long by 1½ins. wide. The flowers do not open till late autumn and are dullish white.

The variety Gloire de Versailles is well known as, on the whole, about the best of the hardy deciduous ones, giving as it does a continuous display of its richly blue flowers from July to October. It is one of the hardiest of all ceanothuses and, of course, does not need a wall. But, visiting a garden in Suffolk a few years ago in July, I was astonished by seeing there a house-front covered with it from the ground to 12ft. up and producing the most gorgeous mass of blue blossom I ever saw by any wall shrub.

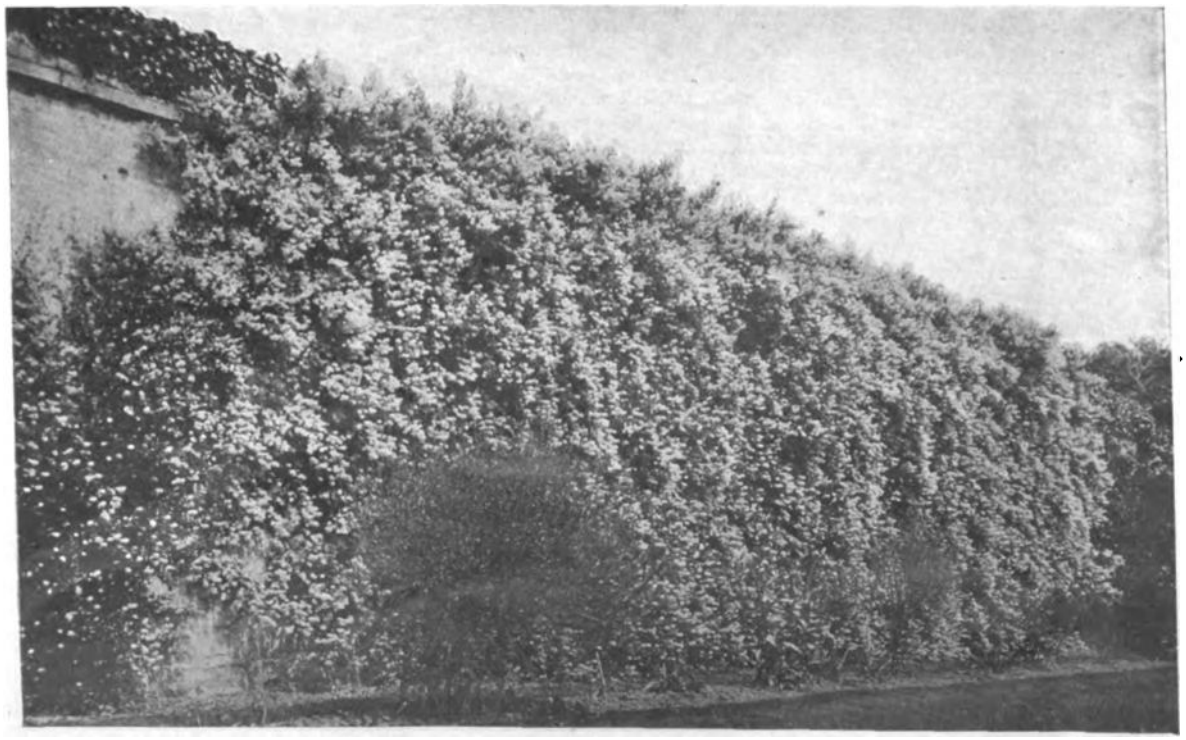
CHIMONANTHUS FRAGRANS.—Although quite hardy, this charming old shrub is often given wall space because it will flower there from December to February, bearing its delightfully fragrant blossoms in abundance. In the typical form they are scarcely 1in. wide, the outer petals greenish yellow, the inner ones purplish; in the variety grandiflorus the flower is of a purer yellow and is half as large again. The shrub is deciduous and should be pruned not later than March.



THE SUN LOVING CARPENTERIA CALIFORNICA.

CLEMATIS.—Being mostly pure climbers, the clematises are not of much use for furnishing walls. They make for the top too quickly, leaving the lower part naked. But where there is plenty of head room, such as is given by the side of a house, rather tender species like C. Armandii may be planted. No species, perhaps, produces so fine an effect on a house front as C. montana, especially if it can be allowed to form heavy masses, the long shoots of the previous season being wreathed from end to end in May with beautiful white blossom. Still, a wall is not essential for it, nor for its rose-coloured var. rubens. Both are hardy, especially the latter, and they can be used to festoon pergolas or allowed to ramble over bushes and trees. The varieties of the Jackmannii group are worth trying on a north wall where, although direct sunlight rarely reaches them, there is plenty of diffused light. I have seen the fine dark one called "Gipsy Queen" flower well in such a position.

(To be continued.)



CEANOTHUS THYRSIFLORUS AT ITS BEST.

THE FIFTY BEST SAXIFRAGES

BY DR. R. LLOYD PRAEGER.

RECENTLY (p. 157 *supra*) I reviewed briefly the whole of the extensive tribe of saxifrages to show from what portions of its populous domain we draw the many beautiful plants which adorn our rock gardens, and how our choice is limited in the search for "fifty best." From what was then said it appears that we rely for our material on only seven subdivisions out of fifteen, these seven subdivisions supplying 120 species out of a known total of over 300. Furthermore, taking into consideration the number and garden value of the species and varieties of each section, it will be admitted that our "fifty best" should be made up something like this: Silvers, 14; Kabschias, 20; mossies, 8; others, 8: Total 50. It is wise to over-represent the "others," since all of them differ widely from the mass of silvers, Kabschias and mossies, and thus help materially to give variety to the collection. Now for an attempt at selection.
